Pass 1	4624	00:02:49.80	00:03:39.92
Symbol table sort	0	00:00:00.61	00:00:00.62
Pass 2	43	00:00:49.46	00:01:04.26
Symbol table output	2	00:00:00.22	00:00:00.25
Psect synopsis output	0	00:00:00.81	00:00:01.11
Cross-reference output	0	00:00:00.00	00:00:00.00
Assembler run totals	5594	00:03:42.04	00:04:48.73

The working set limit was 7800 pages.
1975230 bytes (3858 pages) of virtual memory were used to buffer the intermediate code.
There were 30 pages of symbol table space allocated to hold 372 non-local and 225 local symbols.
14199 source lines were read in Pass 1, producing 525 object records in Pass 2.
102 pages of virtual memory were used to define 47 macros.

```
                              +---------------------------+
                              ! Macro library statistics !
                              +---------------------------+

Macro library name                          Macros defined
------------------                          --------------
DISK$UCODPACK00:[VAX750]COMETMAC.MLB;805              47

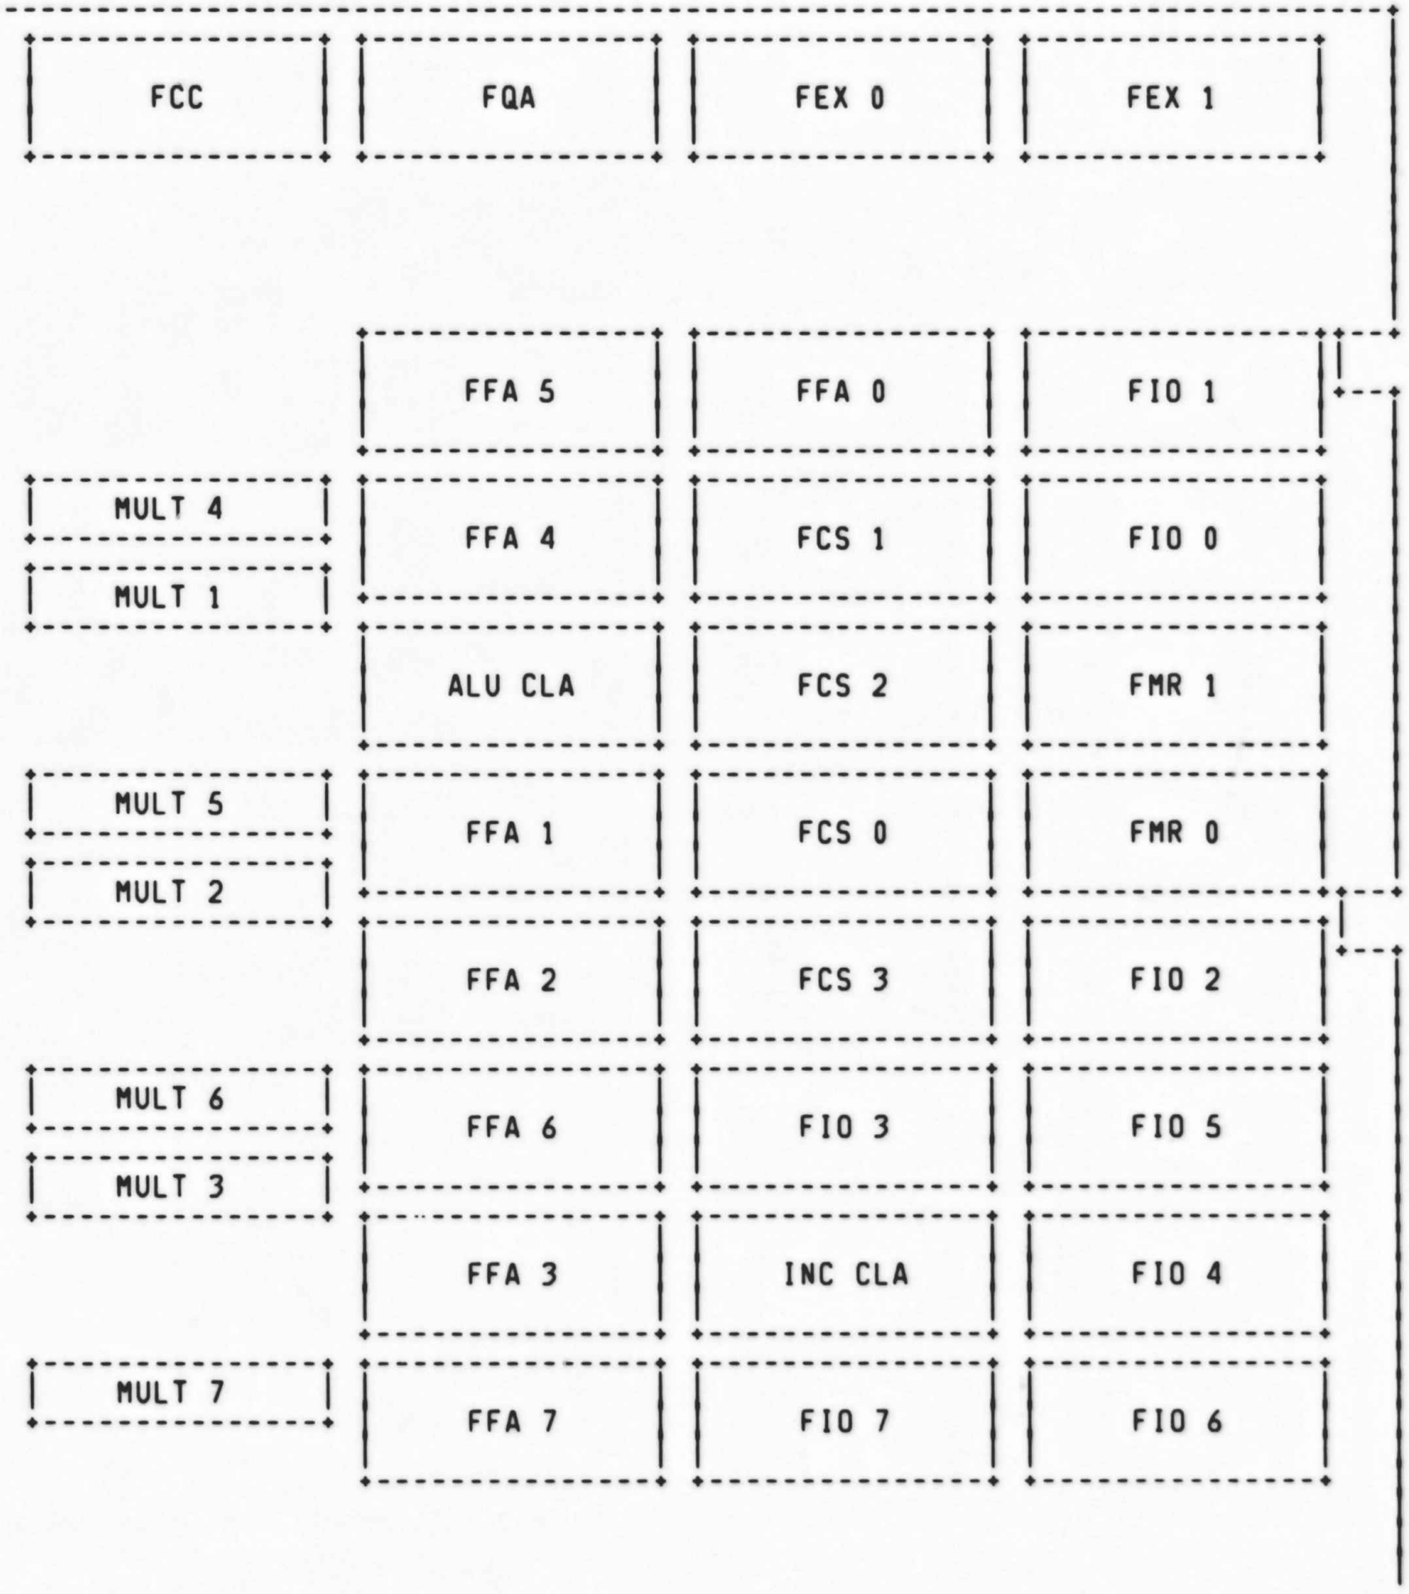
0000     27 ;
0000     28 ; REVISION HISTORY
0000     29 ;
0000     30 ; 00-01 Tom Groetzinger 4-FEB-1980
0000     31 ;       Started file.
0000     32 ;
0000     33 ; 00-02 Dave Spain      27-FEB-1980
0000     34 ;       Added CS BUS INTEGRITY test.
0000     35 ;
0000     36 ; 00-03 Tom Groetzinger 12-MAR-1980
0000     37 ;       Added five tests.
0000     38 ;
0000     39 ; 00-04 Tom Groetzinger 17-MAR-1980
0000     40 ;       Added SRK,SRM callouts to some tests.
0000     41 ;
0000     42 ; 00-05 Tom Groetzinger 17-MAR-1980
0000     43 ;       Improved tests 7 and 16 to increase coverage due to Westboro feedback
0000     44 ;
0000     45 ; 00-06 Tom Groetzinger 17-MAR-1980
0000     46 ;       Debugged test 16 dueu to major rewrite
0000     47 ;
0000     48 ; 00-07 Tom Groetzinger 17-MAR-1980
0000     49 ;       Added 9 Super Rotator tests
0000     50 ;
0000     51 ; 01-08 Dave Spain       4-APR-80
0000     52 ;       Added 4 Micro-sequencer tests for offical release.
0000     53 ;
0000     54 ; 01-09 Bill Landry     4-APR-1980
0000     55 ;       Added the XB, PREFETCH and IRD tests from ECKAC.SRC so
0000     56 ;       manufacturing can run one tape for DPM.
0000     57 ;
0000     58 ; 00-10 Bill Landry     4-APR-1980
0000     59 ;       Let's save version 1.0 for our first SDC release.
0000     60 ;
0000     61 ; 00-11 Tom Groetzinger 7-APR-1980
0000     62 ;       Added 2 ALK Tests
0000     63 ;
0000     64 ; 00-12 Tom Groetzinger 8-APR-1980
0000     65 ;       Deleted last 2 D Register outputs from ALK Test #6
0000     66 ;
0000     67 ; 00-13 Tom Groetzinger 14-APR-1980
0000     68 ;       Added D Register output to ALK test #6
0000     69 ;
0000     70 ; 00-14 Dave Spain      25-APR-1980
0000     71 ;       Changed mask on the micro-sequencer tests to ignore bit 13 of the
0000     72 ;       Control Store address.
0000     73 ;
0000     74 ; 00-15 Dave Spain      28-APR-1980
0000     75 ;       Fixed bug in ALK Tests 6 and 7 by replacing VSIZE/1 micro order with a
0000     76 ;       SIZE[LONG] macro in micro words 6 and 3 respectively.
0000     77 ;
0000     78 ; 00-16 Dave Spain      29-APR-1980
```

```
0000     79 ;       Changed mask on CS address for Instruction Address Decode test from
0000     80 ;       3FFF to 1FFF to ignore bit 13 of Control Store address.
0000     81 ;
0000     82 ; 00-17 Dave Spain      30-APR-1980
0000     83 ;       Added CCS module to error callout for Control Store Bus Integrity test.
0000     84 ;
0000     85 ; 00-18 Dave Spain       9-MAY-1980
0000     86 ;       Added SRM gate array to error callout routine in RTMP0 and RTEMP
0000     87 ;       Sratchpad tests.
0000     88 ;
0000     89 ; 00-19 Bill Landry     10-JUN-1980
0000     90 ;       Added RDM tests to beginning of tape
0000     91 ;
0000     92 ; 01-00 Bill Landry/Dave Spain  13-JUN-1980
0000     93 ;       Added macro file to title section and compatibility mode IRD tests
0000     94 ;       then submitted to RELEASE ENGINERRING.
0000     95 ;
0000     96 ; 01-01 Dave Spain      19-JUN-1980
0000     97 ;       Fixed prefetch incrementer test to clear out cache data after every
0000     98 ;       prefetch. This will prevent the test from mistaking bad addresses from
0000     99 ;       good ones.
0000    100 ;
0000    101 ; 01-02 Dave Spain       2-JUL-1980
0000    102 ;       Added CM Second IRDX tests to file.
0000    103 ;
0000    104 ; 01-03 Dave Spain      18-AUG-1980
0000    105 ;       Added CM branch test to file.
0000    106 ;
0000    107 ; 01-04 Dave Spain      10-SEPT-1980
0000    108 ;       Fixed "DEFAULT MTEMP0 TEST"
0000    109 ;
0000    110 ; 01-05 Bill Landry     11-SEPT-1980
0000    111 ;       Revised RDM to CMI tests
0000    112 ;
0000    113 ; 02-00 Dave Spain      28-SEPT-1980
0000    114 ;       Added rotator tests to file and submitted to SDC.
0000    115 ;
0000    116 ; 02-01 Dave Spain      28-OCT-1980
0000    117 ;       Added QV flag to tests to be run by manufacturing.
0000    118 ;
0000    119 ; 02-02 Bill Landry     10-NOV-1980
0000    120 ;       Added tests for TOK and SAC gate arrays.
0000    121 ;
0000    122 ; 02-03 Bill Landry     13-NOV-1980
0000    123 ;       Added test of REI CHECK
0000    124 ;
0000    125 ; 03-00 Dave Spain      17-NOV-1980
0000    126 ;       Added rotator tests 23-28 and released to SDC.
0000    127 ;
0000    128 ; 03-01 Dave Spain      10-DEC-1980
0000    129 ;       Added rotator tests 29-42.
0000    130 ;
0000    131 ; 03-02 Bill Landry     11-DEC-1980
0000    132 ;       Fixed bug in CS ADDRESS test
0000    133 ;
```

```
0000   134 ; 03-03 Dave Spain      12-DEC-1980
0000   135 ;       Enhanced Rotator Test 1 to call out ALP slices.
0000   136 ;
0000   137 ; 03-04 Bill Landry     16-DEC-1980
0000   138 ;       Added DSIZE ROM tests
0000   139 ;
0000   140 ; 03-05 Bill Landry     31-DEC-1980
0000   141 ;       Last great act of 80. Separated DPM and RDM tests into two files.
0000   142 ;
0000   143 ; 04-00 Bill Landry     5-JAN-1981
0000   144 ;       Submitted to RELEASE ENGINERRING
0000   145 ;
0000   146 ; 04-01 Bill Landry     14-JAN-1981
0000   147 ;       Revised INTERVAL TIMER INTERRUPT TEST to fix bug caused by INT PEND
0000   148 ;       ECO
0000   149 ;
0000   150 ; 04-02 Dave Spain      16-JAN-1981
0000   151 ;       Fixed error callout in CS Parity Error, XB, and Prefetch Incrementer
0000   152 ;       tests and added seven new rotator tests.
0000   153 ;
0000   154 ; 04-03 Bill Landry     4-FEB-1981
0000   155 ;       Added tests for CCC gate array
0000   156 ;
0000   157 ; 04-04 Dave Spain      9-FEB-1981
0000   158 ;       Changed the names of rotator tests 23-33.
0000   159 ;
0000   160 ; 04-05 Bill Landry     24-FEB-1981
0000   161 ;       Added tests for DPM discrete branching logic.
0000   162 ;
0000   163 ; 04-06 Bill Landry     27-FEB-1981
0000   164 ;       Added tests for branching logic in PHB gate array.
0000   165 ;
0000   166 ; 05-00 Dave Spain       1-MAR-1981
0000   167 ;       Added 5 SRK status rotator tests and submitted to SDC.
0000   168 ;
0000   169 ; 05-01 Dave Spain      25-MAR-1981
0000   170 ;       Fixed a loop on test bug in the Alu Functions Test by adding a LDFIELD
0000   171 ;       pseudo-op that reinitializes the ROT field in Subtest 1.
0000   172 ;
0000   173 ; 05-02 Bill Landry     25-MAR-1981
0000   174 ;       Fixed bug in BUT/NO.FPA test.  I was branching on the wrong conditions.
0000   175 ;
0000   176 ; 05-03 Dave Spain      14-APR-1981
0000   177 ;       Cleaned up documentation for R Scratchpads Write All Cells Test.
0000   178 ;
0000   179 ; 06-00 Bill Landry     2-MAY-1981
0000   180 ;       Added SPA branching, CON registers, TU58 registers, and CCS PARITY
0000   181 ;       tests.  Submitted to Release Engineering.
0000   182 ;
0000   183 ; 06-01 Dave Spain      17-JUN-1981
0000   184 ;       Replaced the old IRD1 Instruction Address Decode test with two new
0000   185 ;       tests that toggle the PSL's FPD bit and can handle an FPA.
0000   186 ;
0000   187 ; 06-02 Bill Landry     19-AUG-1981
0000   188 ;       Fixed bugs created by introduction of FPA option.
```

```
0000    189 ;       Replaced all references to COMET with the word CPU.
0000    190 ;       Fixed typing error in vbus data of CPU CLOCK TEST.
0000    191 ;       Submitted to RELEASE ENGINEERING.
0000    192 ;
0000    193 ; 06-03 Bill Landry     24-SEPT-1981
0000    194 ;       Fixed potential clock problem with FPA in Z BIT TEST 1.
0000    195 ;
0000    196 ; 06-04 Bill Landry     9-OCT-1981
0000    197 ;       Added changes for ECO L0002-TW002
0000    198 ;
0000    199 ; 07-00 Bill Landry     31-OCT-1981
0000    200 ;       Removed changes for ECO L0002-TW002.  ECO is on hold.
0000    201 ;       Added tests for FPA to CPU interface logic
0000    202 ;       Moved WCS test to MIC tape
0000    203 ;       Submitted to RELEASE ENGINEERING.
0000    204 ;
0000    205 ; 07-01 Bill Landry     13-NOV-1981
0000    206 ;       Stopped release of 7.0
0000    207 ;       Added FPA TRAP LOGIC TEST
0000    208 ;       Enhanced error messages for FPA
0000    209 ;       Resubmitted to RELEASE ENGINEERING
0000    210 ;
0000    211 ; 07-02 Bill Landry     20-NOV-1981
0000    212 ;       Stopped release of 7.1
0000    213 ;       Enhanced FPA ENABLE/DISABLE TEST to check for MSEQ INIT
0000    214 ;       Resubmitted to RELEASE ENGINEERING
0000    215 ;
0000    216 ; 07-03 Dave Shull      26-Mar-1982
0000    217 ;       Added the ERRLOOP pseudo to the Rotator Extract tests which were
0000    218 ;       missing these and couldn't be looped on.
0000    219 ;
0000    220 ; 07-04 Dave Shull      05-Apr-1982
0000    221 ;       Removed all BEGINSA and ENDSA pseudo's.
0000    222 ;       Submitted to RELEASE ENGINEERING
0000    223 ;
0000    224 ; 07-05 Dave Shull      21-May-1982
0000    225 ;       Add a subtest to the Micro Sequencer Stack Test that will test bits
0000    226 ;       11 and 12 of the micro stack.
0000    227 ;
0000    228 ; 07-06 Dave Shull      24-May-1982
0000    229 ;       Changed documentation in the CM Odd Address BUT Test to reflect the
0000    230 ;       ECO L0002-TW002
0000    231 ;
0000    232 ; 08-00 Dave Shull      18-Jun-1982
0000    233 ;       Added 10 new tests.  Two of those tests are an addition to the existing
0000    234 ;       IRD1 rom tests.  These 2 new tests check the signal ROM OS INH H.
0000    235 ;       The other 8 new tests check the validity of the IRDX ROMs.  They check
0000    236 ;       both the address and the signal ROM OS INH H.
0000    237 ;
0000    238 ; 08-01 Dave Shull      22-Jun-1982
0000    239 ;       Added a subtest to the Register Backup Stack test that will check the
0000    240 ;       bit that records Increment/Decrement of the GPR.
0000    241 ;
0000    242 ; 09-00 Dave Shull      03-Nov-1982
0000    243 ;       Added two new Tests for coverage the new PCS (L0008) module.
```

```
0000   244 ;
0000   245 ; 09-01 Dave Smith      15-May-1983
0000   246 ;       Correct DCS in ALK test 3,6,7. Disabled ALP's on the WBUS.
0000   247 ;--
0000     1          .SBTTL  ""
```



```
0000      3          .SBTTL  "DIAGNOSTIC MICROCODE MACROS"
0000      4 ;++
0000      5 ; Revision History
0000      6 ;
0000      7 ; 28    Dave Spain      22-Jun-82
0000      8 ;       Removed LOAD FPA SIGN REG and LOAD FPA SIGN REGS macros.
0000      9 ;       Decided not to use them.
0000     10 ;
0000     11 ; 27    Dave Spain      15-Jun-82
0000     12 ;       Added LOAD FPA SIGN REG and LOAD FPA SIGN REGS macros.
0000     13 ;
0000     14 ; 26    Dave Spain      19-May-82
0000     15 ;       Added M[]_FPA macro.
0000     16 ;
0000     17 ; 25    Rich Lewis      23-Feb-82
0000     18 ;       Added PSL_WB, M[]_R[].OR.NIB0(M), WB_FPA CCR, WB_FPA TCR, Q_R[].ASL.P,
0000     19 ;       RDM_M[].XZ.OR.R[], FPA_WB macros
0000     20 ;
0000     21 ; 24    Dave Spain      02-Feb-82
0000     22 ;       Added FPA_R[]+M[] macro.
0000     23 ;
0000     24 ; 23    Bill Landry     22-OCT-81
0000     25 ;       Added PSL_RDM macro
0000     26 ;
0000     27 ; 22    Dave Spain       5 Oct 81
0000     28 ;       Added RDM_FPA and FPA_M[] FPA_RDM macros.
0000     29 ;
0000     30 ; 21    Bill Landry     29 Sept 81
0000     31 ;       Added FPA macro, FPA_M[] FPA_R[].
0000     32 ;
0000     33 ; 20    Dave Spain      14 Aug 81
0000     34 ;       Added the TESTFPA [] macro.
0000     35 ;
0000     36 ; 19    Dave Spain      18 July 81
0000     37 ;       Added the following FPA macros, FPA_RDM and FPA_R[].
0000     38 ;
0000     39 ; 18    Dave Spain      24 Sept 80
0000     40 ;       Added RDM_Q macro. This macro uses the ALU.
0000     41 ;
0000     42 ; 17    Bill Landry     23 Sept 80
0000     43 ;       Added macro VA_VA-ZLIT0[] for testing memory in decending order.
0000     44 ;
0000     45 ; 16    Dave Spain      27 August 80
0000     46 ;       Changed RDM_Q macro to RDM_Q Q_D. This more accurately reflects macro.
0000     47 ;
0000     48 ; 15    Bill Landry     4 June 80
0000     49 ;       Deleted BUS/PRB.RD.PTE from macro CLRTB.VA_VA and CLRCH.VA_VA to
0000     50 ;       satisfy validity checks.
0000     51 ;
0000     52 ; 14    Dave Spain      23 May 80
0000     53 ;       Added BUS/PRB.RD.PTE to the clear cache and clear TB macros for Mr.
0000     54 ;       Bill.
0000     55 ;
0000     56 ; 13    Dave Spain      14 Apr 80
0000     57 ;       Added SIZE[] or VSIZE/1 to some macros. This allows version 65 of
```

```
0000     58 ;       the COMET micro-code defines to run.
0000     59 ;
0000     60 ; 12    Bill Landry      1 Apr 80
0000     61 ;       Added BUS/PRB.RD micro order to RDM_TB macro to compensate for timing
0000     62 ;       problem in ADD gate array.  This is not an APRIL FOOL!
0000     63 ;
0000     64 ; 11    Dave Spain      27 Mar 80
0000     65 ;       Fixed TB macro's to include MSRC/VA to prevent validity failure.
0000     66 ;
0000     67 ; 10    Bill Landry     19 Mar 80
0000     68 ;       Added Q_R[].RL.P and VA_Q.OR.R[]
0000     69 ;
0000     70 ; 09    Bill Landry     19 Mar 80
0000     71 ;       Deleted TB_R[].RL.P.OR.D
0000     72 ;
0000     73 ; 08    Bill Landry     18 Mar 80
0000     74 ;       Added VA_R[].RL.P
0000     75 ;
0000     76 ; 07    Bill Landry     07 Mar 80
0000     77 ;       Added Q_M[].RL.PTE
0000     78 ;
0000     79 ; 06    Dave Spain      06 Mar 80
0000     80 ;       Changed TB_R[].RL.P macro to TB_R[].RL.P.OR.D.
0000     81 ;
0000     82 ; 05    Dave Spain      03 Mar 80
0000     83 ;       Added TB_R[].RL.P macro for Bill Landry.
0000     84 ;
0000     85 ; 04    Dave Spain      22 Feb 80
0000     86 ;       Added CLRTB.VA_R[] macro for Bill Landry.
0000     87 ;
0000     88 ; 03    Dave Spain      30 Jan 80
0000     89 ;       Added Tom Groetzinger's macro definitions.
0000     90 ;
0000     91 ; 02    Dave Spain      30 Jan 80
0000     92 ;       Added Tony Vezza's macro definitions.
0000     93 ;
0000     94 ; 01    Dave Spain      29 Jan 80
0000     95 ;       Macros initiated.

0011  1109 ; LOGIC DESCRIPTION:
0011  1110 ;
0011  1111 ;       THESE TEST PATTERNS WERE GENERATED USING A LOGIC SIMULATOR.  SO IF
0011  1112 ;       YOU ATTEMPT TO READ THE VAX SRM AND TRY AN CORRELATE THE INSTRUCTIONS
0011  1113 ;       USED VERSUS CONDITIONS CODES IT REALLY WON'T MAKE ANY SENSE.  THE
0011  1114 ;       ATTEMPT HERE IS TO TEST THE INTERNAL WORKINGS OF THE CCC GATE ARRAY.
0011  1115 ;       ANY FAILUES SHOULD BE CONFINED TO THIS ARRAY OR THE INSTRUCTION
0011  1116 ;       REGISTER FEEDING IT.  IF YOU GET A FAILURE IN LOOP 5 AND 12 YOU MIGHT
0011  1117 ;       SUSPECT THE FPA ENABLE SIGNAL INTO THE CCC GATE ARRAY.  THIS TEST
0011  1118 ;       ATTEMPTS TO DISABLE THE FPA BEFORE IT CHECKS THE CONDITION CODES.
0011  1119 ;
0011  1120 ;
0011  1121 ; ASSUMPTIONS:
0011  1122 ;
0011  1123 ;       THIS TEST ASSUMES THE PREFETCH LOGIC IS OPERATIONAL.
0011  1124 ;
0011  1125 ; ERROR DESCRIPTION:

0011   2048 ;*******************************************************************************
0011   2049 ;++
0011   2050 ;
0011   2051 ; FUNCTIONAL DESCRIPTION:
0011   2052 ;
0011   2053 ;       THIS TEST VERIFIES THAT THE C BIT IN THE CCC GATE ARRAY SETS PROPERLY
0011   2054 ;       FOR NATIVE MODE INSTRUCTIONS USING CC/CCOP1.CCBR_SIGND MICRO ORDER.
0011   2055 ;
0011   2056 ;
0011   2057 ; TEST ALGORITHM:
0011   2058 ;
0011   2059 ;       1.  CREATE A TEST LOOP OF 32
0011   2060 ;       2.  MODIFY THE MICRO CODE FOR EACH LOOP THROUGH THE TEST
0011   2061 ;       3.  LOAD THE NEW MICRO CODE INTO THE RDM DCS
0011   2062 ;       4.  SAVE THE LOOP COUNT
0011   2063 ;       5.  MOVE THE LOOP COUNT TO THE RDM WDREG
0011   2064 ;       6.  EXECUTE THE DCS PROGRAM
0011   2065 ;               a.  DISABLE ^P INTERRUPTS
0011   2066 ;               b.  SET THE IPL TO 1F AND MODE TO NATIVE
0011   2067 ;               c.  MOVE THE LOOP COUNT TO THE RTEMPS
0011   2068 ;               d.  LOAD THE PLATCH WITH 2
0011   2069 ;               e.  ROTATE THE LOOP COUNT LEFT BY 2 TO FORM A CACHE ADDRESS
0011   2070 ;               f.  LOAD THE PC WITH THE CACHE ADDRESS TO FORCE PREFETCH
0011   2071 ;               g.  PERFORM IRD1TEST TO LOAD THE IR REGISTER
0011   2072 ;               h.  LOAD THE Q REGISTER WITH TEST DATA
0011   2073 ;               i.  ADD THE Q REGISTER TO ONE OF THE RTEMPS TO CREATE THE
0011   2074 ;                       TEST CONDITIONS WHILE PERFORMING CCOP1.
0011   2075 ;               j.  READ THE PSL TO THE RDM
0011   2076 ;       7.  TEST THE PSL C BIT FOR CORRECT STATE
0011   2077 ;       8.  IF NO ERROR GO TO STEP 2 FOR THE REMAINING TEST PATTERNS

001C  2558 ;*******************************************************************************
001C  2559 ;++
001C  2560 ;
001C  2561 ; FUNCTIONAL DESCRIPTION:
001C  2562 ;
001C  2563 ;       THIS TEST VERIFIES THAT THE CCBR0 SIGNAL FROM THE CCC GATE ARRAY CAN
001C  2564 ;       BE SET PROPERLY FOR NATIVE MODE BRANCH CONDITIONS.
001C  2565 ;
001C  2566 ;
001C  2567 ; TEST ALGORITHM:
001C  2568 ;
001C  2569 ;       1.  CREATE A TEST LOOP OF 24
001C  2570 ;       2.  MODIFY THE MICRO CODE FOR EACH LOOP THROUGH THE TEST
001C  2571 ;       3.  LOAD THE NEW MICRO CODE INTO THE RDM DCS
001C  2572 ;       4.  SAVE THE LOOP COUNT
001C  2573 ;       5.  MOVE THE LOOP COUNT TO THE RDM WDREG
001C  2574 ;       6.  EXECUTE THE DCS PROGRAM
001C  2575 ;               a.  SET THE PSL TO THE TEST CONDITIONS
001C  2576 ;               b.  DISABLE ^P INTERRUPTS
001C  2577 ;               c.  MOVE THE LOOP COUNT TO THE RTEMPS
001C  2578 ;               d.  LOAD THE PLATCH WITH 2
001C  2579 ;               e.  ROTATE THE LOOP COUNT LEFT BY 2 TO FORM A CACHE ADDRESS
001C  2580 ;               f.  LOAD THE PC WITH THE CACHE ADDRESS TO FORCE PREFETCH
001C  2581 ;               g.  PERFORM IRD1TEST TO LOAD THE IR REGISTER
001C  2582 ;               h.  BUT ON THE BRANCH CONDITONS
001C  2583 ;       7.  TEST THE CS ADDRESS FOR THE CORRECT BRANCH
001C  2584 ;       8.  IF NO ERROR GO TO STEP 2 FOR THE REMAINING TEST PATTERNS

0023  2797 ;*******************************************************************************
0023  2798 ;++
0023  2799 ;
0023  2800 ; FUNCTIONAL DESCRIPTION:
0023  2801 ;
0023  2802 ;       THIS TEST VERIFIES THAT THE CCBR0 SIGNAL FROM THE CCC GATE ARRAY CAN
0023  2803 ;       BE SET PROPERLY BY COMPATABILITY MODE BRANCH CONDITIONS.
0023  2804 ;
0023  2805 ;
0023  2806 ; TEST ALGORITHM:
0023  2807 ;
0023  2808 ;       1.  CREATE A TEST LOOP OF 29
0023  2809 ;       2.  MODIFY THE MICRO CODE FOR EACH LOOP THROUGH THE TEST
0023  2810 ;       3.  LOAD THE NEW MICRO CODE INTO THE RDM DCS
0023  2811 ;       4.  SAVE THE LOOP COUNT
0023  2812 ;       5.  MOVE THE LOOP COUNT TO THE RDM WDREG
0023  2813 ;       6.  EXECUTE THE DCS PROGRAM
0023  2814 ;               a.  SET THE PSL TO NATIVE MODE AND IPL EQUAL 1F
0023  2815 ;               b.  DISABLE ^P INTERRUPTS
0023  2816 ;               c.  MOVE THE LOOP COUNT TO THE RTEMPS
0023  2817 ;               d.  LOAD THE PLATCH WITH 2
0023  2818 ;               e.  ROTATE THE LOOP COUNT LEFT BY 2 TO FORM A CACHE ADDRESS
0023  2819 ;               f.  LOAD THE PC WITH THE CACHE ADDRESS TO FORCE PREFETCH
0023  2820 ;               g.  PERFORM IRD1TEST TO LOAD THE IR REGISTER
0023  2821 ;               h.  SET THE PSL TO THE TEST CONDITIONS
0023  2822 ;               i.  BUT ON THE BRANCH CONDITIONS
0023  2823 ;       7.  TEST THE CS ADDRESS FOR THE CORRECT BRANCH
0023  2824 ;       8.  IF NO ERROR GO TO STEP 2 FOR THE REMAINING TEST PATTERNS
0023  2825 ;

0026  4169 ;*******************************************************************************
0026  4170 ;++
0026  4171 ;
0026  4172 ; FUNCTIONAL DESCRIPTION
0026  4173 ;
0026  4174 ;       This test examines the logic that implements the BUT/SRKSTA microbranch
0026  4175 ;       on SLATCH and PLATCH data. The BUT/SRKSTA microbranch is performed by
0026  4176 ;       placing two bits called SRKSTA<1:0> onto the Control Store Address Bus
0026  4177 ;       (CSADDR) bits <1:0>.
0026  4178 ;
0026  4179 ; TEST ALGORITHM
0026  4180 ;
0026  4181 ;       This test is implemented in six subtests. Each subtest examines one
0026  4182 ;       type of SLATCH and PLATCH SRK status microbranch. The microbranches
0026  4183 ;       performed by these subtests are:
0026  4184 ;
0026  4185 ;       Subtest 1 SRKSTA<1> = SL.EQ.0 and SRKSTA<0> = (PL<4:0>+SL).GT.32
0026  4186 ;       Subtest 2 SRKSTA<1> = SL.EQ.0 and SRKSTA<0> = PL<5>
0026  4187 ;       Subtest 3 SRKSTA<1> = 0 and SRKSTA<0> = PL<5>
0026  4188 ;       Subtest 4 SRKSTA<1> = PL<4:0>.EQ.0 and SRKSTA<0> = PL<5>
0026  4189 ;       Subtest 5 SRKSTA<1> = PL<4:0>.EQ.0 and SRKSTA<0> = 0
0026  4190 ;       Subtest 6 SRKSTA<1> = SL.EQ.0 and SRKSTA<0> = undefined
0026  4191 ;
0026  4192 ;       Together they provide a full test of all the SLATCH and PLATCH SRK
0026  4193 ;       status microbranches. The algorithm for each is specified below:
0026  4194 ;
0026  4195 ;       Subtests 1 - 6
0026  4196 ;
0026  4197 ;        1. Initialize the CPU. (Subtest 1 only)
0026  4198 ;        2. Start signature analysis.
0026  4199 ;        3. Prepare a loop on I for all the ROT microorders that can branch
0026  4200 ;           on the particular S and P latch function under test.
0026  4201 ;        4. Load the ROT field of the test microinstruction for the function
0026  4202 ;           to be tested for this iteration of the I loop.
0026  4203 ;        5. Load the test microinstruction into DCS at address 1807.
0026  4204 ;        6. Prepare a loop on J for the number of S and P latch data patterns
0026  4205 ;           needed to check the branch under test.
0026  4206 ;        7. Load the LONLIT field of a LONLIT_[0] microinstruction with a
0026  4207 ;           P latch data pattern from a table indexed by J.
0026  4208 ;        8. Load the LONLIT field of a LONLIT_[0] microinstruction with an
0026  4209 ;           S latch data pattern from a table indexed by J.
0026  4210 ;        9. Load the microword prepared in step 7 into DCS at address 1801.
0026  4211 ;       10. Load the microword prepared in step 8 into DCS at address 1804.
0026  4212 ;       11. Loop on error from this point.
0026  4213 ;       12. Execute the microcode to do the following:
0026  4214 ;                1. Load the LONLIT register with a PLATCH data pattern.
0026  4215 ;                2. Write the LONLIT register to the rotator's PLATCH.
0026  4216 ;                3. Write the PLATCH into MTEMP0.
0026  4217 ;                4. Load the LONLIT register with an SLATCH data pattern.
0026  4218 ;                5. Write the LONLIT register to the rotator's SLATCH.
0026  4219 ;                6. Write the SLATCH into MTEMP1.
0026  4220 ;                7. Source zero onto the RBUS and MBUS and perform the rotator
0026  4221 ;                   and BUT functions that execute the microbranch to be tested.
0026  4222 ;       13. Mask out bit 13 (and bit 0 for Subtest 6 only) of the microaddress
```

```
0026  4223 ;           in the Control Store Address Trap Register (CSTRP) and then compare
0026  4224 ;           it against the expected address from a table indexed by J.
0026  4225 ;       14. If the two do not match signal an error.
0026  4226 ;       15. Continue the loop on J for the remaining S and P latch data.
0026  4227 ;       16. Continue the loop on I for the remaining rotator functions.
0026  4228 ;       17. Stop signature analysis.
0026  4229 ;       18. End of test, skip to the next test. (Subtest 6 only)
0026  4230 ;
0026  4231 ; TEST DATA
0026  4232 ;
0026  4233 ;       The tables given below show the contents of the ROT field of the micro-
0026  4234 ;       word based on the index I and the contents of the PLATCH, SLATCH, and
0026  4235 ;       CS ADDRESS BUS based on the index J for each subtest. All data are
0026  4236 ;       given in hex unless noted otherwise.

0026  4380 ;
0026  4381 ; LOGIC DESCRIPTION
0026  4382 ;
0026  4383 ;       A combination of discrete logic on the DPM module and logic internal to
0026  4384 ;       the SRK gate array is used to implement the SRK status microbranch.
0026  4385 ;       The SRK gate array contains the S and P latches and also receives the
0026  4386 ;       ROT field of the microword. This enables it to generate the signals
0026  4387 ;       SRK ST1 and SRK ST0 based on the contents of the S and P latches and
```

```
                        4388 ;       ROT field of the microword. These signals are passed to two 74S151
                        4389 ;       8 to 1 multiplexers that can drive bits 0 and 1 of the CS ADDRESS BUS.
                        4390 ;       The mux that receives SRK ST1 will select this signal and enable its
                        4391 ;       output whenever it receives a BUT/SRKSTA microbranch. The mux that
                        4392 ;       receives SRK ST0 will select this signal and enable its output whenever
                        4393 ;       it receives a BUT/SRKSTA or BUT/CCBR0.SRKSTA0 microbranch. For this
                        4394 ;       test only BUT/SRKSTA is used.
                        4395 ;

0026  4738 ;*******************************************************************************
0026  4739 ;++
0026  4740 ;
0026  4741 ; FUNCTIONAL DESCRIPTION
0026  4742 ;
0026  4743 ;       This test examines the SRK logic that implements the BUT/SRKSTA micro-
0026  4744 ;       branches based on DSIZE, SBUS and WBUS data. The BUT/SRKSTA microbranch
0026  4745 ;       is performed by placing two bits called SRKSTA<1:0> onto the Control
0026  4746 ;       Store Address Bus (CSADDR) bits <1:0>.
0026  4747 ;
0026  4748 ; TEST ALGORITHM
0026  4749 ;
0026  4750 ;       This test has been divided into three subtests. Each subtest examines
0026  4751 ;       one of the three types of SRK status microbranches mentioned above.
0026  4752 ;       The microbranches performed by each subtest are:
0026  4753 ;
0026  4754 ;       Subtest 1 SRKSTA<1> = DSIZE<1> and SRKSTA<0> = DSIZE<0>
0026  4755 ;       Subtest 2 SRKSTA<1> = S<3:0>.NE.0 and SRKSTA<0> = S<3:0>.NE.(11,13)
0026  4756 ;       Subtest 3 SRKSTA<1> = WX<31:16>.NE.0 and SRKSTA<0> = WX<15:00>.NE.0
0026  4757 ;
0026  4758 ;       Subtest 1
0026  4759 ;
0026  4760 ;        1. Initialize the CPU.
0026  4761 ;        2. Start signature analysis.
0026  4762 ;        3. Prepare a loop on I for 8 rotator functions that perform DSIZE
0026  4763 ;           branching.
0026  4764 ;        4. Load the ROT field of the test microinstruction for the function
0026  4765 ;           to be tested for this iteration of the I loop.
0026  4766 ;        5. Prepare a loop on J for the 3 data types that can be specified in
0026  4767 ;           the DTYPE field of the test microinstruction.
0026  4768 ;        6. Load the DTYPE field of the test microinstruction for the DSIZE
0026  4769 ;           microbranch to be tested for this iteration of the J loop.
0026  4770 ;        7. Load the 3 test microinstructions into DCS starting at 1800.
0026  4771 ;        8. Loop on error from here.
0026  4772 ;        9. Execute the following microcode to perform a DSIZE microbranch:
0026  4773 ;               1. Put zeros on the RBUS, load DSIZE from the DTYPE field and
0026  4774 ;                  then perform the rotator and BUT functions that execute the
0026  4775 ;                  microbranch to be tested.
0026  4776 ;       10. Mask out bit 13 of the microaddress in the Control Store Address
0026  4777 ;           Trap Register (CSTRP) and then compare it against the expected
0026  4778 ;           address from a table indexed by J.
0026  4779 ;       11. If the two do not match signal an error.
0026  4780 ;       12. Continue the loop on J for the remaining DTYPE datums.
0026  4781 ;       13. Continue the loop on I for the remaining DSIZE microbranches.
0026  4782 ;       14. Stop signature analysis.
0026  4783 ;
0026  4784 ;       Subtest 2
0026  4785 ;
0026  4786 ;        1. Start signature analysis.
0026  4787 ;        2. Load DCS with four test microinstructions starting at address 1800.
0026  4788 ;        3. Prepare to loop on I for 24 MBUS to SBUS data patterns.
0026  4789 ;        4. Load the WDREG with an MBUS to SBUS test pattern from a table
0026  4790 ;           indexed by I.
0026  4791 ;        5. Loop on error from here.
```

```
0026  4792 ;        6. Execute the following test microcode:
0026  4793 ;              1. NOP to get the CPU clock up to speed.
0026  4794 ;              2. Load MTEMP0 with the pattern in WDREG.
0026  4795 ;              3. Put MTEMP0 onto the MBUS, execute a ROT/BCDSWP microorder,
0026  4796 ;                 and write the resulting SBUS contents to RTEMP1, while
0026  4797 ;                 performing the BUT/SRKSTA microbranch on an address of 1800.
0026  4798 ;              4. Stop the CPU clock to halt.
0026  4799 ;        7. Mask out bit 13 of the microaddress in the Control Store Address
0026  4800 ;           Trap Register (CSTRP) and then compare it against the expected
0026  4801 ;           address from a table indexed by I.
0026  4802 ;        8. If the two do not match, signal an error.
0026  4803 ;        9. Continue the loop on I for the remaining MBUS to SBUS patterns.
0026  4804 ;       10. Stop signature analysis.
0026  4805 ;
0026  4806 ;       Subtest 3
0026  4807 ;
0026  4808 ;        1. Start signature analysis.
0026  4809 ;        2. Prepare a loop on I for the 2 ROT microorders that can branch on
0026  4810 ;           the contents of WX<31:16> and WX<15:00>.
0026  4811 ;        3. Load the ROT field of the test microinstruction for the function
0026  4812 ;           to be tested by this iteration of the I loop.
0026  4813 ;        4. Load the four test microinstructions into DCS starting at 1800.
0026  4814 ;        5. Prepare to loop on J for 19 WX<31:00> test patterns.
0026  4815 ;        6. Load a WX<31:00> test pattern from a table indexed by J into the
0026  4816 ;           WDREG.
0026  4817 ;        7. Loop on error from here.
0026  4818 ;        8. Execute the following test microcode:
0026  4819 ;              1. NOP to get the CPU clock up to speed.
0026  4820 ;              2. Load RTEMP0 with the WX pattern in WDREG.
0026  4821 ;              3. Put RTEMP0 onto the RBUS, route it through the ALU to the
0026  4822 ;                 WBUS, perform the rotator function under test, write the
0026  4823 ;                 data on the WBUS to MTEMP1 and perform the BUT microbranch.
0026  4824 ;              4. Stop the CPU clock to halt.
0026  4825 ;        9. Mask out bit 13 of the microaddress in the Control Store Address
0026  4826 ;           Trap Register (CSTRP) and then compare it against the expected
0026  4827 ;           address from a table indexed by J.
0026  4828 ;       10. If the two do not match, signal an error.
0026  4829 ;       11. Continue the loop on J for the remaining WX test patterns.
0026  4830 ;       12. Continue the loop on I for the remaining rotator functions.
0026  4831 ;       13. Stop signature analysis.
0026  4832 ;       14. End of test, skip to the next test.

0026  4913 ; LOGIC DESCRIPTION
0026  4914 ;
0026  4915 ;       A combination of discrete logic on the DPM module and logic internal to
0026  4916 ;       the SRK gate array is used to implement the SRK status microbranch.
0026  4917 ;       The SRK gate array receives the ROT field of the microword and the
0026  4918 ;       signals D SIZE<1:0>, SBUS<7:0> and WMUXZ<3:0>. This enables it to
0026  4919 ;       generate the signals SRK ST1 and SRK ST0 for each of the subtests in
0026  4920 ;       this test. These signals are passed to two 74S151 8 to 1 multiplexers
0026  4921 ;       that can drive bits 0 and 1 of the CS ADDRESS BUS. The mux that
0026  4922 ;       receives SRK ST1 will select this signal and enable its output whenever
0026  4923 ;       it receives a BUT/SRKSTA microbranch. The mux that receives SRK ST0
0026  4924 ;       will select this signal and enable its output whenever it receives a
0026  4925 ;       BUT/SRKSTA or BUT/CCBR0.SRKSTA0 microbranch. For this test only
0026  4926 ;       BUT/SRKSTA is used.
0026  4927 ;
0026  4928 ; ASSUMPTIONS
0026  4929 ;
0026  4930 ;       This test assumes the following DPM logic has been tested and is
0026  4931 ;       working; the RBUS, MBUS, SBUS and WBUS; the ALPCTL microorders WX_R.Q_D
0026  4932 ;       and WX_S.Q_0; the rotator's data path; and the dual port scratchpad
0026  4933 ;       registers TEMP0 and TEMP1.
0026  4934 ;
0026  4935 ; ERROR DESCRIPTION
0026  4936 ;
0026  4937 ;       On error this tell will call out the SRK gate array and will type out

0026  5136 ;*******************************************************************************
0026  5137 ;++
0026  5138 ;
0026  5139 ; FUNCTIONAL DESCRIPTION
0026  5140 ;
0026  5141 ;       This test examines the SRK logic that implements the BUT/SRKSTA micro-
0026  5142 ;       branch based on the ASCII SIGN CHECK function. The BUT/SRKSTA micro-
0026  5143 ;       branch is performed by placing two bits called SRKSTA<1:0> onto the
0026  5144 ;       Control Store Address Bus (CSADDR) bits <1:0>.
0026  5145 ;
0026  5146 ; TEST ALGORITHM
0026  5147 ;
0026  5148 ;       The test algorithm is as follows:
0026  5149 ;
0026  5150 ;        1. Initialize the CPU.
0026  5151 ;        2. Start signature analysis.
0026  5152 ;        3. Prepare a loop on I for the 8 rotator microorders that perform the
0026  5153 ;           ASCII SIGN CHECK function on the SRK status lines.
0026  5154 ;        4. Load the ROT field of the test microinstruction for the function to
0026  5155 ;           be tested for this iteration of the I loop.
0026  5156 ;        5. Load the test microinstruction into DCS at address 1801.
0026  5157 ;        6. Prepare to loop on J for the 24 WBUS patterns used to examine the
0026  5158 ;           ASCII SIGN CHECK function.
0026  5159 ;        7. Load a WBUS test pattern from a table indexed by J into the WDREG.
0026  5160 ;        8. Loop on error from here.
0026  5161 ;        9. Execute the following microcode:
0026  5162 ;               1. NOP to get the CPU clock up to speed.
0026  5163 ;               2. Source WDREG onto the WBUS, write it into RTEMP0 and execute
0026  5164 ;                  the rotator and BUT/SRKSTA operations needed to perform the
0026  5165 ;                  ASCII SIGN CHECK function.
0026  5166 ;               3. Stop the CPU clock to halt.
0026  5167 ;       10. Mask out bit 13 of the microaddress in the Control Store Address
0026  5168 ;           Trap Register (CSTRP) and compare it against the expected data from
0026  5169 ;           a table indexed by J.
0026  5170 ;       11. If the two do not match, signal an error.
0026  5171 ;       12. Continue the loop on J for the remaining WBUS patterns.
0026  5172 ;       13. Continue the loop on I for the remaining rotator functions.
0026  5173 ;       14. Stop signature analysis.
0026  5174 ;       15. End of the test, skip to the next test.
0026  5175 ;
0026  5176 ; TEST DATA
0026  5177 ;
0026  5178 ;       The data used in this test consists of 24 WBUS data patterns that are
0026  5179 ;       input to the rotator from the WBUS in order to examine the ASCII SIGN
0026  5180 ;       CHECK SRK status microbranch. The data is as follows:

0026  5220 ; LOGIC DESCRIPTION
0026  5221 ;
0026  5222 ;       A combination of discrete logic on the DPM module and logic internal to
0026  5223 ;       the SRK gate array is used to implement the SRK status microbranch
0026  5224 ;       ASCII SIGN CHECK. The SRK gate array receives the ROT field of the
0026  5225 ;       microword and WBUS<7:0>. This enables it to generate the signals SRK
0026  5226 ;       ST1 and SRK ST0 based on the contents of the ROT field and WBUS<7:0>.
0026  5227 ;       These signals are passed to two 74S151 8 to 1 multiplexers that can
0026  5228 ;       drive bits 0 and 1 of the CS ADDRESS BUS. The mux that receives SRK ST1
0026  5229 ;       will select this signal and enable its output whenever it receives a
0026  5230 ;       BUT/SRKSTA microbranch. The mux that receives SRK ST0 will select this
0026  5231 ;       signal and enable its output whenever it receives a BUT/SRKSTA or
0026  5232 ;       BUT/CCBR0.SRKSTA0 microbranch. For this test only BUT/SRKSTA is used.
0026  5233 ;
0026  5234 ; ASSUMPTIONS
0026  5235 ;
0026  5236 ;       This test assumes the following DPM logic has been tested and is
0026  5237 ;       working; the RBUS and WBUS; and the dual port scratchpad register
0026  5238 ;       RTEMP0.
0026  5239 ;
0026  5240 ; ERROR DESCRIPTION
0026  5241 ;
0026  5242 ;       On error this tell will call out the SRK gate array and will type out
0026  5243 ;       the following information:
0026  5244 ;
```

0026  5426 ; LOGIC DESCRIPTION
0026  5427 ;
0026  5428 ;       A combination of discrete logic on the DPM module and logic internal to
0026  5429 ;       the SRK gate array is used to implement the SRK status microbranch WBUS
0026  5430 ;       RANGE CHECK. The SRK gate array receives the ROT field of the microword
0026  5431 ;       and WBUS bits <7:0>. This enables it to generate the signals SRK ST1
0026  5432 ;       and SRK ST0 based on the contents of the ROT field and WBUS<7:0>. These
0026  5433 ;       signals are passed to two 74S151 8 to 1 multiplexers that can drive
0026  5434 ;       bits 0 and 1 of the CS ADDRESS BUS. The mux that receives SRK ST1 will
0026  5435 ;       select this signal and enable its output whenever it receives a
0026  5436 ;       BUT/SRKSTA microbranch. The mux that receives SRK ST0 will select this
0026  5437 ;       signal and enable its output whenever it receives a BUT/SRKSTA or
0026  5438 ;       BUT/CCBR0.SRKSTA0 microbranch. For this test only BUT/SRKSTA is used.
0026  5439 ;
0026  5440 ; ASSUMPTIONS
0026  5441 ;
0026  5442 ;       This test assumes the following DPM logic has been tested and is
0026  5443 ;       working; the RBUS and WBUS; and the dual port scratchpad register
0026  5444 ;       RTEMP0.
0026  5445 ;
0026  5446 ; ERROR DESCRIPTION
0026  5447 ;
0026  5448 ;       On error this tell will call out the SRK gate array and will type out
```

0026  5545 ;*******************************************************************************
0026  5546 ;++
0026  5547 ;
0026  5548 ; FUNCTIONAL DESCRIPTION
0026  5549 ;
0026  5550 ;       This test examines the SRK logic that implements the BUT/SRKSTA micro-
0026  5551 ;       branch based on the ABSOLUTE VALUE CHECK function. The BUT/SRKSTA
0026  5552 ;       microbranch is performed by placing two bits called SRKSTA<1:0> onto
0026  5553 ;       the Control Store Address Bus (CSADDR) bits <1:0>.
0026  5554 ;
0026  5555 ; TEST ALGORITHM
0026  5556 ;
0026  5557 ;       The test algorithm is as follows:
0026  5558 ;
0026  5559 ;        1. Initialize the CPU.
0026  5560 ;        2. Start signature analysis.
0026  5561 ;        3. Prepare a loop on I for the 16 rotator microorders that perform the
0026  5562 ;           ABSOLUTE VALUE CHECK function on the SRK status lines.
0026  5563 ;        4. Load the ROT field of the test microinstruction for the function to
0026  5564 ;           be tested for this iteration of the I loop.
0026  5565 ;        5. Load the test microinstruction into DCS at address 1801.
0026  5566 ;        6. Prepare to loop on J for the 54 WBUS patterns used to examine the
0026  5567 ;           ABSOLUTE VALUE CHECK function.
0026  5568 ;        7. Load a WBUS test pattern from a table indexed by J into the WDREG.
0026  5569 ;        8. Loop on error from here.
0026  5570 ;        9. Execute the following microcode:
0026  5571 ;               1. NOP to get the CPU clock up to speed.
0026  5572 ;               2. Source WDREG onto the WBUS, write it into RTEMP0 and execute
0026  5573 ;                  the rotator and BUT/SRKSTA operations needed to perform the
0026  5574 ;                  ABSOLUTE VALUE CHECK function.
0026  5575 ;               3. Stop the CPU clock to halt.
0026  5576 ;       10. Mask out bit 13 of the microaddress in the Control Store Address
0026  5577 ;           Trap Register (CSTRP) and compare it against the expected data from
0026  5578 ;           a table indexed by J.
0026  5579 ;       11. If the two do not match, signal an error.
0026  5580 ;       12. Continue the loop on J for the remaining WBUS patterns.
0026  5581 ;       13. Continue the loop on I for the remaining rotator functions.
0026  5582 ;       14. Stop signature analysis.
0026  5583 ;       15. End of the test, skip to the next test.
0026  5584 ;
0026  5585 ; TEST DATA
0026  5586 ;
0026  5587 ;       The data used in this test consists of 24 WBUS data patterns that are
0026  5588 ;       input to the rotator from the WBUS in order to examine the ABSOLUTE
0026  5589 ;       VALUE CHECK SRK status microbranch. The data is as follows:
0026  5590 ;
0026  5591 ;            INDEX I    ROTATOR FUNCTION
0026  5592 ;

0026  5667 ; LOGIC DESCRIPTION
0026  5668 ;
0026  5669 ;       A combination of discrete logic on the DPM module and logic internal to
0026  5670 ;       the SRK gate array is used to implement the SRK status microbranch
0026  5671 ;       ABSOLUTE VALUE CHECK. The SRK gate array receives the ROT field of the
0026  5672 ;       microword and WBUS bits <7:0>. This enables it to generate the signals
0026  5673 ;       SRK ST1 and SRK ST0 based on the contents of the ROT field and
0026  5674 ;       WBUS<7:0>. These signals are passed to two 74S151 8 to 1 multiplexers
0026  5675 ;       that can drive bits 0 and 1 of the CS ADDRESS BUS. The mux that
0026  5676 ;       receives SRK ST1 will select this signal and enable its output whenever
0026  5677 ;       it receives a BUT/SRKSTA microbranch. The mux that receives SRK ST0
0026  5678 ;       will select this signal and enable its output whenever it receives a
0026  5679 ;       BUT/SRKSTA or BUT/CCBR0.SRKSTA0 microbranch. For this test only
0026  5680 ;       BUT/SRKSTA is used.
0026  5681 ;
0026  5682 ; ASSUMPTIONS
0026  5683 ;
0026  5684 ;       This test assumes the following DPM logic has been tested and is
0026  5685 ;       working; the RBUS, MBUS and WBUS; and the dual port scratchpad register
0026  5686 ;       RTEMP0.
0026  5687 ;
0026  5688 ; ERROR DESCRIPTION
0026  5689 ;
0026  5690 ;       On error this tell will call out the SRK gate array and will type out
0026  5691 ;       the following information:
0026  5692 ;
0026  5693 ;       EXPECTED CONTROL STORE ADDRESS
0026  5694 ;       RECEIVED CONTROL STORE ADDRESS
0026  5695 ;       INDEX I (INDEX TO THE ROTATOR FUNCTION UNDER TEST)
0026  5696 ;       INDEX J (INDEX TO THE WBUS AND CS ADDRESS DATA TABLES)
0026  5697 ;       RTEMP0 (WBUS CONTENTS)
0026  5698 ;

0013  5974 ;
0013  5975 ;
0013  5976 ; LOGIC DESCRIPTION:
0013  5977 ;
0013  5978 ;       THIS TEST USES THE DPM BRANCHING LOGIC THAT GATES PREVIOUS DESTINATION
0013  5979 ;       INHIBIT ONTO CS ADDRESS BIT <0>.  SUBTEST #1 IS PRETTY STRAIGHTFORWARD,
0013  5980 ;       BUT SUBTEST #2 GETS A LITTLE MESSY DUE TO THE TIMING CONTRAINTS OF THE
0013  5981 ;       RDM.  SINCE THE SUBTEST MICRO TRAPS AND WE NEED TO LOOK AT PREV DEST
0013  5982 ;       INH ON THE NEXT MICRO CYCLE WE WERE UNABLE TO USE THE BRSTCLK PSEUDO
0013  5983 ;       OP.  WHAT THIS MEANS TO YOU IS THAT YOU WILL NOT BE ABLE TO SET A SCOPE
0013  5984 ;       SYNC POINT IN THIS SUBTEST.  HOWEVER, THERE IS NOT A GREAT DEAL OF
0013  5985 ;       LOGIC INVOLVED HERE AND MY BET IS THAT BY JUST LOOPING ON THE SUBTEST
0013  5986 ;       YOU SHOULD BE ABLE TO SCOPE OUT THE PROBLEM.
0013  5987 ;
0013  5988 ;

Assembler run totals	10011	00:03:02.49	00:06:53.83

The working set limit was 4096 pages.
1792105 bytes (3501 pages) of virtual memory were used to buffer the intermediate code.
There were 30 pages of symbol table space allocated to hold 367 non-local and 295 local symbols.
8723 source lines were read in Pass 1, producing 497 object records in Pass 2.
99 pages of virtual memory were used to define 46 macros.

Macro library statistics

Macro library name	Macros defined
DISK$UCODPACK00:[VAX750]COMETMAC.MLB;805	46
SYS$COMMON:[SYSLIB]STARLET.MLB;2	0
TOTALS (all libraries)	46

1899 GETS were required to define 46 macros.

0000     26 ; DPM MICRO-DIAGNOSTIC PACKAGE
0000     27 ;
0000     28 ; REVISION HISTORY
0000     29 ;
0000     30 ; 00-01 Tom Groetzinger 4-FEB-1980
0000     31 ;       Started file.
0000     32 ;
0000     33 ; 00-02 Dave Spain      27-FEB-1980
0000     34 ;       Added CS BUS INTEGRITY test.
0000     35 ;
0000     36 ; 00-03 Tom Groetzinger 12-MAR-1980
0000     37 ;       Added five tests.
0000     38 ;
0000     39 ; 00-04 Tom Groetzinger 17-MAR-1980
0000     40 ;       Added SRK,SRM callouts to some tests.
0000     41 ;
0000     42 ; 00-05 Tom Groetzinger 17-MAR-1980
0000     43 ;       Improved tests 7 and 16 to increase coverage due to Westboro feedback
0000     44 ;
0000     45 ; 00-06 Tom Groetzinger 17-MAR-1980
0000     46 ;       Debugged test 16 dueu to major rewrite
0000     47 ;
0000     48 ; 00-07 Tom Groetzinger 17-MAR-1980
0000     49 ;       Added 9 Super Rotator tests
0000     50 ;
0000     51 ; 01-08 Dave Spain       4-APR-80
0000     52 ;       Added 4 Micro-sequencer tests for offical release.
0000     53 ;
0000     54 ; 01-09 Bill Landry     4-APR-1980
0000     55 ;       Added the XB, PREFETCH and IRD tests from ECKAC.SRC so
0000     56 ;       manufacturing can run one tape for DPM.
0000     57 ;
0000     58 ; 00-10 Bill Landry     4-APR-1980
0000     59 ;       Let's save version 1.0 for our first SDC release.
0000     60 ;
0000     61 ; 00-11 Tom Groetzinger 7-APR-1980
0000     62 ;       Added 2 ALK Tests
0000     63 ;
0000     64 ; 00-12 Tom Groetzinger 8-APR-1980
0000     65 ;       Deleted last 2 D Register outputs from ALK Test #6
0000     66 ;
0000     67 ; 00-13 Tom Groetzinger 14-APR-1980
0000     68 ;       Added D Register output to ALK test #6
0000     69 ;
0000     70 ; 00-14 Dave Spain      25-APR-1980
0000     71 ;       Changed mask on the micro-sequencer tests to ignore bit 13 of the
0000     72 ;       Control Store address.
0000     73 ;
0000     74 ; 00-15 Dave Spain      28-APR-1980
0000     75 ;       Fixed bug in ALK Tests 6 and 7 by replacing VSIZE/1 micro order with a
0000     76 ;       SIZE[LONG] macro in micro words 6 and 3 respectively.
0000     77 ;
0000     78 ; 00-16 Dave Spain      29-APR-1980
```

```
0000     79 ;       Changed mask on CS address for Instruction Address Decode test from
0000     80 ;       3FFF to 1FFF to ignore bit 13 of Control Store address.
0000     81 ;
0000     82 ; 00-17 Dave Spain      30-APR-1980
0000     83 ;       Added CCS module to error callout for Control Store Bus Integrity test.
0000     84 ;
0000     85 ; 00-18 Dave Spain       9-MAY-1980
0000     86 ;       Added SRM gate array to error callout routine in RTMP0 and RTEMP
0000     87 ;       Sratchpad tests.
0000     88 ;
0000     89 ; 00-19 Bill Landry     10-JUN-1980
0000     90 ;       Added RDM tests to beginning of tape
0000     91 ;
0000     92 ; 01-00 Bill Landry/Dave Spain  13-JUN-1980
0000     93 ;       Added macro file to title section and compatibility mode IRD tests
0000     94 ;       then submitted to RELEASE ENGINERRING.
0000     95 ;
0000     96 ; 01-01 Dave Spain      19-JUN-1980
0000     97 ;       Fixed prefetch incrementer test to clear out cache data after every
0000     98 ;       prefetch. This will prevent the test from mistaking bad addresses from
0000     99 ;       good ones.
0000    100 ;
0000    101 ; 01-02 Dave Spain       2-JUL-1980
0000    102 ;       Added CM Second IRDX tests to file.
0000    103 ;
0000    104 ; 01-03 Dave Spain      18-AUG-1980
0000    105 ;       Added CM branch test to file.
0000    106 ;
0000    107 ; 01-04 Dave Spain      10-SEPT-1980
0000    108 ;       Fixed "DEFAULT MTEMP0 TEST"
0000    109 ;
0000    110 ; 01-05 Bill Landry     11-SEPT-1980
0000    111 ;       Revised RDM to CMI tests
0000    112 ;
0000    113 ; 02-00 Dave Spain      28-SEPT-1980
0000    114 ;       Added rotator tests to file and submitted to SDC.
0000    115 ;
0000    116 ; 02-01 Dave Spain      28-OCT-1980
0000    117 ;       Added QV flag to tests to be run by manufacturing.
0000    118 ;
0000    119 ; 02-02 Bill Landry     10-NOV-1980
0000    120 ;       Added tests for TOK and SAC gate arrays.
0000    121 ;
0000    122 ; 02-03 Bill Landry     13-NOV-1980
0000    123 ;       Added test of REI CHECK
0000    124 ;
0000    125 ; 03-00 Dave Spain      17-NOV-1980
0000    126 ;       Added rotator tests 23-28 and released to SDC.
0000    127 ;
0000    128 ; 03-01 Dave Spain      10-DEC-1980
0000    129 ;       Added rotator tests 29-42.
0000    130 ;
0000    131 ; 03-02 Bill Landry     11-DEC-1980
0000    132 ;       Fixed bug in CS ADDRESS test
0000    133 ;
```

```
0000   134 ; 03-03 Dave Spain      12-DEC-1980
0000   135 ;       Enhanced Rotator Test 1 to call out ALP slices.
0000   136 ;
0000   137 ; 03-04 Bill Landry     16-DEC-1980
0000   138 ;       Added DSIZE ROM tests
0000   139 ;
0000   140 ; 03-05 Bill Landry     31-DEC-1980
0000   141 ;       Last great act of 80. Separated DPM and RDM tests into two files.
0000   142 ;
0000   143 ; 04-00 Bill Landry     5-JAN-1981
0000   144 ;       Submitted to RELEASE ENGINERRING
0000   145 ;
0000   146 ; 04-01 Bill Landry     14-JAN-1981
0000   147 ;       Revised INTERVAL TIMER INTERRUPT TEST to fix bug caused by INT PEND
0000   148 ;       ECO
0000   149 ;
0000   150 ; 04-02 Dave Spain      16-JAN-1981
0000   151 ;       Fixed error callout in CS Parity Error, XB, and Prefetch Incrementer
0000   152 ;       tests and added seven new rotator tests.
0000   153 ;
0000   154 ; 04-03 Bill Landry     4-FEB-1981
0000   155 ;       Added tests for CCC gate array
0000   156 ;
0000   157 ; 04-04 Dave Spain      9-FEB-1981
0000   158 ;       Changed the names of rotator tests 23-33.
0000   159 ;
0000   160 ; 04-05 Bill Landry     24-FEB-1981
0000   161 ;       Added tests for DPM discrete branching logic.
0000   162 ;
0000   163 ; 04-06 Bill Landry     27-FEB-1981
0000   164 ;       Added tests for branching logic in PHB gate array.
0000   165 ;
0000   166 ; 05-00 Dave Spain       1-MAR-1981
0000   167 ;       Added 5 SRK status rotator tests and submitted to SDC.
0000   168 ;
0000   169 ; 05-01 Dave Spain      25-MAR-1981
0000   170 ;       Fixed a loop on test bug in the Alu Functions Test by adding a LDFIELD
0000   171 ;       pseudo-op that reinitializes the ROT field in Subtest 1.
0000   172 ;
0000   173 ; 05-02 Bill Landry     25-MAR-1981
0000   174 ;       Fixed bug in BUT/NO.FPA test.  I was branching on the wrong conditions.
0000   175 ;
0000   176 ; 05-03 Dave Spain      14-APR-1981
0000   177 ;       Cleaned up documentation for R Scratchpads Write All Cells Test.
0000   178 ;
0000   179 ; 06-00 Bill Landry     2-MAY-1981
0000   180 ;       Added SPA branching, CON registers, TU58 registers, and CCS PARITY
0000   181 ;       tests.  Submitted to Release Engineering.
0000   182 ;
0000   183 ; 06-01 Dave Spain      17-JUN-1981
0000   184 ;       Replaced the old IRD1 Instruction Address Decode test with two new
0000   185 ;       tests that toggle the PSL's FPD bit and can handle an FPA.
0000   186 ;
0000   187 ; 06-02 Bill Landry     19-AUG-1981
0000   188 ;       Fixed bugs created by introduction of FPA option.
```

```
0000   189 ;       Replaced all references to COMET with the word CPU.
0000   190 ;       Fixed typing error in vbus data of CPU CLOCK TEST.
0000   191 ;       Submitted to RELEASE ENGINEERING.
0000   192 ;
0000   193 ; 06-03 Bill Landry     24-SEPT-1981
0000   194 ;       Fixed potential clock problem with FPA in Z BIT TEST 1.
0000   195 ;
0000   196 ; 06-04 Bill Landry     9-OCT-1981
0000   197 ;       Added changes for ECO L0002-TW002
0000   198 ;
0000   199 ; 07-00 Bill Landry     31-OCT-1981
0000   200 ;       Removed changes for ECO L0002-TW002.  ECO is on hold.
0000   201 ;       Added tests for FPA to CPU interface logic
0000   202 ;       Moved WCS test to MIC tape
0000   203 ;       Submitted to RELEASE ENGINEERING.
0000   204 ;
0000   205 ; 07-01 Bill Landry     13-NOV-1981
0000   206 ;       Stopped release of 7.0
0000   207 ;       Added FPA TRAP LOGIC TEST
0000   208 ;       Enhanced error messages for FPA
0000   209 ;       Resubmitted to RELEASE ENGINEERING
0000   210 ;
0000   211 ; 07-02 Bill Landry     20-NOV-1981
0000   212 ;       Stopped release of 7.1
0000   213 ;       Enhanced FPA ENABLE/DISABLE TEST to check for MSEQ INIT
0000   214 ;       Resubmitted to RELEASE ENGINEERING
0000   215 ;
0000   216 ; 07-03 Dave Shull      26-Mar-1982
0000   217 ;       Added the ERRLOOP pseudo to the Rotator Extract tests which were
0000   218 ;       missing these and couldn't be looped on.
0000   219 ;
0000   220 ; 07-04 Dave Shull      05-Apr-1982
0000   221 ;       Removed all BEGINSA and ENDSA pseudo's.
0000   222 ;       Submitted to RELEASE ENGINEERING
0000   223 ;
0000   224 ; 07-05 Dave Shull      21-May-1982
0000   225 ;       Add a subtest to the Micro Sequencer Stack Test that will test bits
0000   226 ;       11 and 12 of the micro stack.
0000   227 ;
0000   228 ; 07-06 Dave Shull      24-May-1982
0000   229 ;       Changed documentation in the CM Odd Address BUT Test to reflect the
0000   230 ;       ECO L0002-TW002
0000   231 ;
0000   232 ; 08-00 Dave Shull      18-Jun-1982
0000   233 ;       Added 10 new tests.  Two of those tests are an addition to the existing
0000   234 ;       IRD1 rom tests.  These 2 new tests check the signal ROM OS INH H.
0000   235 ;       The other 8 new tests check the validity of the IRDX ROMs.  They check
0000   236 ;       both the address and the signal ROM OS INH H.
0000   237 ;
0000   238 ; 08-01 Dave Shull      22-Jun-1982
0000   239 ;       Added a subtest to the Register Backup Stack test that will check the
0000   240 ;       bit that records Increment/Decrement of the GPR.
0000   241 ;
0000   242 ; 09-00 Dave Shull      03-Nov-1982
0000   243 ;       Added two new Tests for coverage the new PCS (L0008) module.
```

0000     5 ; Revision History
0000     6 ;
0000     7 ; 28    Dave Spain      22-Jun-82
0000     8 ;       Removed LOAD FPA SIGN REG and LOAD FPA SIGN REGS macros.
0000     9 ;       Decided not to use them.
0000    10 ;
0000    11 ; 27    Dave Spain      15-Jun-82
0000    12 ;       Added LOAD FPA SIGN REG and LOAD FPA SIGN REGS macros.
0000    13 ;
0000    14 ; 26    Dave Spain      19-May-82
0000    15 ;       Added M[]_FPA macro.
0000    16 ;
0000    17 ; 25    Rich Lewis      23-Feb-82
0000    18 ;       Added PSL_WB, M[]_R[].OR.NIB0(M), WB_FPA CCR, WB_FPA TCR, Q_R[].ASL.P,
0000    19 ;       RDM_M[].XZ.OR.R[], FPA_WB macros
0000    20 ;
0000    21 ; 24    Dave Spain      02-Feb-82
0000    22 ;       Added FPA_R[]+M[] macro.
0000    23 ;
0000    24 ; 23    Bill Landry     22-OCT-81
0000    25 ;       Added PSL_RDM macro
0000    26 ;
0000    27 ; 22    Dave Spain       5 Oct 81
0000    28 ;       Added RDM_FPA and FPA_M[] FPA_RDM macros.
0000    29 ;
0000    30 ; 21    Bill Landry     29 Sept 81
0000    31 ;       Added FPA macro, FPA_M[] FPA_R[].
0000    32 ;
0000    33 ; 20    Dave Spain      14 Aug 81
0000    34 ;       Added the TESTFPA [] macro.
0000    35 ;
0000    36 ; 19    Dave Spain      18 July 81
0000    37 ;       Added the following FPA macros, FPA_RDM and FPA_R[].
0000    38 ;
0000    39 ; 18    Dave Spain      24 Sept 80
0000    40 ;       Added RDM_Q macro. This macro uses the ALU.
0000    41 ;
0000    42 ; 17    Bill Landry     23 Sept 80
0000    43 ;       Added macro VA_VA-ZLIT0[] for testing memory in decending order.
0000    44 ;
0000    45 ; 16    Dave Spain      27 August 80
0000    46 ;       Changed RDM_Q macro to RDM_Q Q_D. This more accurately reflects macro.
0000    47 ;
0000    48 ; 15    Bill Landry     4 June 80
0000    49 ;       Deleted BUS/PRB.RD.PTE from macro CLRTB.VA_VA and CLRCH.VA_VA to
0000    50 ;       satisfy validity checks.
0000    51 ;
0000    52 ; 14    Dave Spain      23 May 80
0000    53 ;       Added BUS/PRB.RD.PTE to the clear cache and clear TB macros for Mr.
0000    54 ;       Bill.
0000    55 ;
0000    56 ; 13    Dave Spain      14 Apr 80
0000    57 ;       Added SIZE[] or VSIZE/1 to some macros. This allows version 65 of
```

```
0000     58 ;       the COMET micro-code defines to run.
0000     59 ;
0000     60 ; 12    Bill Landry      1 Apr 80
0000     61 ;       Added BUS/PRB.RD micro order to RDM_TB macro to compensate for timing
0000     62 ;       problem in ADD gate array.  This is not an APRIL FOOL!
0000     63 ;
0000     64 ; 11    Dave Spain      27 Mar 80
0000     65 ;       Fixed TB macro's to include MSRC/VA to prevent validity failure.
0000     66 ;
0000     67 ; 10    Bill Landry     19 Mar 80
0000     68 ;       Added Q_R[].RL.P and VA_Q.OR.R[]
0000     69 ;
0000     70 ; 09    Bill Landry     19 Mar 80
0000     71 ;       Deleted TB_R[].RL.P.OR.D
0000     72 ;
0000     73 ; 08    Bill Landry     18 Mar 80
0000     74 ;       Added VA_R[].RL.P
0000     75 ;
0000     76 ; 07    Bill Landry     07 Mar 80
0000     77 ;       Added Q_M[].RL.PTE
0000     78 ;
0000     79 ; 06    Dave Spain      06 Mar 80
0000     80 ;       Changed TB_R[].RL.P macro to TB_R[].RL.P.OR.D.
0000     81 ;
0000     82 ; 05    Dave Spain      03 Mar 80
0000     83 ;       Added TB_R[].RL.P macro for Bill Landry.
0000     84 ;
0000     85 ; 04    Dave Spain      22 Feb 80
0000     86 ;       Added CLRTB.VA_R[] macro for Bill Landry.
0000     87 ;
0000     88 ; 03    Dave Spain      30 Jan 80
0000     89 ;       Added Tom Groetzinger's macro definitions.
0000     90 ;
0000     91 ; 02    Dave Spain      30 Jan 80
0000     92 ;       Added Tony Vezza's macro definitions.
0000     93 ;
0000     94 ; 01    Dave Spain      29 Jan 80
0000     95 ;       Macros initiated.

                        002B  1583 ;*****************************************************************************
                        002B  1584 ;++
                        002B  1585 ;
                        002B  1586 ; FUNCTIONAL DESCRIPTION
                        002B  1587 ;
                        002B  1588 ;       This test will examine the ROMS that implement a native mode IRD1 when
                        002B  1589 ;       the First Part Done (FPD) bit of the PSL is set to zero.
                        002B  1590 ;
                        002B  1591 ; TEST ALGORITHM
                        002B  1592 ;
                        002B  1593 ;       This test is implemented in three subtests. The first subtest examines
                        002B  1594 ;       the IRD1 ROMS when the CPU's Floating Point Accelerator (FPA) is not
                        002B  1595 ;       present. The second subtest examines the ROMS when there is an FPA
                        002B  1596 ;       present and it has been disabled. The third subtest examines the ROMS
                        002B  1597 ;       when the FPA is present and enabled. The test algorithm executes as
                        002B  1598 ;       follows:
                        002B  1599 ;
                        002B  1600 ;        1. Initialize the CPU. This will clear the FPD bit in the PSL.
                        002B  1601 ;        2. Execute the following microcode to initialize an FPA:
                        002B  1602 ;                1. NOP to get the CPU up to speed.
                        002B  1603 ;                2. Load four NOP opcodes into the longlit register for XB0.
                        002B  1604 ;                3. Zero the VA.
                        002B  1605 ;                4. Write the NOPS for XB0 into cache at address 0.
                        002B  1606 ;                5. Increment the VA by 4.
                        002B  1607 ;                6. Validate the next location for XB1 prefetch by writing
                        002B  1608 ;                   NOPS to cache at address 4.
                        002B  1609 ;                7. Zero the PC to initiate the instruction prefetch that
                        002B  1610 ;                   writes XB0 and XB1 from cache.
                        002B  1611 ;                8. Execute an IRD1TEST cycle to decode the NOP in XB0.
                        002B  1612 ;                   This will prepare an FPA to be enabled or disabled.
                        002B  1613 ;                9. Halt.
                        002B  1614 ;        3. Execute the following microcode to test for an FPA presence:
                        002B  1615 ;                10. NOP to get the CPU up to speed.
                        002B  1616 ;                11. BUT/NO.FPA,NEXT/1800
                        002B  1617 ;                12. STOP.CLOCK to halt.
                        002B  1618 ;        4. Perform a masked comparison of the address in the Control Store
                        002B  1619 ;           Address Trace Register (CSTRP) against the expected address for the
                        002B  1620 ;           FPA not present.
                        002B  1621 ;        5. If the two do not match, then there is an FPA so branch to
                        002B  1622 ;           Subtest 2. Otherwise continue on to Subtest 1.
                        002B  1623 ;
                        002B  1624 ;       Subtest 1
                        002B  1625 ;
                        002B  1626 ;        6. Loop on error from here.
                        002B  1627 ;        7. Re-execute the microcode in step 3 to test the FPA enable bit.
                        002B  1628 ;        8. Perform a masked comparison of the CSTRP with the expected address
                        002B  1629 ;           for the FPA disabled.
                        002B  1630 ;        9. If the two do not match then there is a problem with the FPA/CPU
                        002B  1631 ;           interface so signal an error.
                        002B  1632 ;       10. Prepare the RDM to expect non-DCS addresses.
                        002B  1633 ;       11. Prepare a loop on I for 256 VAX opcodes.
                        002B  1634 ;       12. Save the loop counter minus one in the RDM memory.
                        002B  1635 ;       13. Load the WDREG with the number saved in RDM memory.
                        002B  1636 ;       14. Loop on error from here.
```

```
002B  1637 ;       15. Execute the following test microcode:
002B  1638 ;             13. NOP to get the CPU up to speed.
002B  1639 ;             14. Load the opcode to be tested from the WDREG to RTEMP1.
002B  1640 ;             15. Load the operands into the longlit register.
002B  1641 ;             16. Move the operands from the longlit register into the
002B  1642 ;                 Q register.
002B  1643 ;             17. Form the test instruction by ORing the opcode in RTEMP1
002B  1644 ;                 (MTEMP1=RTEMP1) with the operands in the Q register and
002B  1645 ;                 write the result back to RTEMP1.
002B  1646 ;             18. Zero the VA.
002B  1647 ;             19. Write the test instruction in RTEMP1 to cache at address 0.
002B  1648 ;             20. Increment the VA by 4.
002B  1649 ;             21. Validate the next location for XB1 prefetch by writing
002B  1650 ;                 zeros to cache at address 4.
002B  1651 ;             22. Zero the PC to initiate the instruction prefetch that
002B  1652 ;                 writes XB0 and XB1 from cache.
002B  1653 ;             23. Write the contents of XB0 to RTEMP0. This will cause the
002B  1654 ;                 PC to increment by 4 and can change the contents of XB0.
002B  1655 ;             24. Rezero the PC to reload XB0 and XB1.
002B  1656 ;             25. Execute a BUT/IRD1 to decode the instruction in XB0.
002B  1657 ;             26. Halt.
002B  1658 ;       16. Perform a masked comparison of the address in the CSTRP register
002B  1659 ;           with the expected control store address for the IRD1.
002B  1660 ;       17. If the two are not equal, signal an error.
002B  1661 ;       18. Continue to loop on I for the remaining VAX opcodes.
002B  1662 ;       19. Skip to the next test.
002B  1663 ;
002B  1664 ;       Subtests 2 and 3
002B  1665 ;
002B  1666 ;       20. Load the WDREG with a longword to perform an FPA disable for
002B  1667 ;           Subtest 2 or an FPA enable for Subtest 3.
002B  1668 ;       21. Loop on error from here.
002B  1669 ;       22. Execute the following microcode to disable the FPA for Subtest 2 or
002B  1670 ;           to enable the FPA for Subtest 3 and to also check the result:
002B  1671 ;                26. NOP to get the CPU up to speed.
002B  1672 ;                27. WCTRL/FPAENABLE_WB5,WB_RDM to write the FPA's enable bit
002B  1673 ;                    with bit 5 of the RDM's WDREG.
002B  1674 ;                28. NOP
002B  1675 ;                29. BUT/NO.FPA,NEXT/1800 to test for FPA enabled.
002B  1676 ;                30. STOP.CLOCK to halt.
002B  1677 ;       23. Perform a masked comparison of the CSTRP with the expected address
002B  1678 ;           for the FPA disabled (Subtest 2) or the FPA enabled (Subtest 3).
002B  1679 ;       24. If the two do not match then there is a problem with the FPA/CPU
002B  1680 ;           interface so signal an error.
002B  1681 ;       25. Prepare the RDM to expect non-DCS addresses.
002B  1682 ;       26. Prepare a loop on I for 256 VAX opcodes.
002B  1683 ;       27. Save the loop counter minus one in the RDM memory.
002B  1684 ;       28. Load the WDREG with the number saved in RDM memory.
002B  1685 ;       29. Loop on error from here.
002B  1686 ;       30. Execute the same test microcode as in Subtest 1 step 15.
002B  1687 ;       31. Perform a masked comparison of the address in the CSTRP register
002B  1688 ;           with the expected control store address for the IRD1.
002B  1689 ;       32. If the two are not equal, signal an error.
002B  1690 ;       33. Continue to loop on I for the remaining VAX opcodes.
002B  1691 ;       34. If this is Subtest 2 then continue on to Subtest 3.
```

```
                     1692 ;          If this is Subtest 3 then skip to the next test.
                     1693 ;
                     1694 ; TEST PATTERNS
                     1695 ;
                     1696 ;       For this test the VAX machine opcodes are generated by a simple count
                     1697 ;       pattern. The opcodes are based on the 256 base machine instructions
                     1698 ;       as specified in the VAX architecture handbook. The generated opcodes
                     1699 ;       are written to the CPU and combined with three bytes of operand
                     1700 ;       data to form a VAX machine instruction. The operands all specify R0 in
                     1701 ;       register mode and are loaded from the CPU's long literal register.
                     1702 ;
                     1703 ;       Also required are two tables of expected control store addresses for
                     1704 ;       each IRD1 Instruction Decode Cycle. One table contains the expected
                     1705 ;       addresses for an IRD1 when the FPA has been disabled, the other for
                     1706 ;       when it is enabled.  The expected control store addresses were obtained
                     1707 ;       from the Native Mode Ird Rom Definition in the CPU microcode.
                     1708 ;
                     1709 ; LOGIC DESCRIPTION
                     1710 ;
                     1711 ;       The CCS ROMS are fed addresses from ROMS on the DPM during instruction
                     1712 ;       decode. The DPM ROMS are addressed by bits <07:00> of the execution
                     1713 ;       buffer. These bits form the opcode for the instruction. For zero and
                     1714 ;       certain single operand instructions the addresses generated by the ROMS
                     1715 ;       will force a jump to execution flows in the microcode. For the rest,
                     1716 ;       operand specifier evaulation addresses will be generated.
                     1717 ;
                     1718 ; ASSUMPTIONS
                     1719 ;
                     1720 ;       This test assumes the following logic has already been tested; the
                     1721 ;       CPU's data path, the cache, the XB, and the IR and OSR.
                     1722 ;
                     1723 ; ERROR DESCRIPTION
                     1724 ;
                     1725 ;       On error this test can type out the following information:
                     1726 ;
                     1727 ;       Failing gate arrays:    IRD
                     1728 ;       Failing modules:        FPA, MIC
                     1729 ;
                     1730 ;       The following data will also by typed:
                     1731 ;
                     1732 ;       EXPECTED CONTROL STORE ADDRESS
                     1733 ;       RECEIVED CONTROL STORE ADDRESS
                     1734 ;       LOOP COUNT (INDEX I)

                        002B  2076 ;
                        002B  2077 ;       This test is implemented in three subtests. The first subtest examines
                        002B  2078 ;       the IRD1 ROMS when the CPU's Floating Point Accelerator (FPA) is not
                        002B  2079 ;       present. The second subtest examines the ROMS when there is an FPA
                        002B  2080 ;       present and it has been disabled. The third subtest examines the ROMS
                        002B  2081 ;       when the FPA is present and enabled. The test algorithm executes as
                        002B  2082 ;       follows:
                        002B  2083 ;
                        002B  2084 ;        1. Initialize the CPU. This will clear the FPD bit in the PSL.
                        002B  2085 ;        2. Execute the following microcode to initialize an FPA:
                        002B  2086 ;                1. NOP to get the CPU up to speed.
                        002B  2087 ;                2. Load four NOP opcodes into the longlit register for XB0.
                        002B  2088 ;                3. Zero the VA.
                        002B  2089 ;                4. Write the NOPS for XB0 into cache at address 0.
                        002B  2090 ;                5. Increment the VA by 4.
                        002B  2091 ;                6. Validate the next location for XB1 prefetch by writing
                        002B  2092 ;                   NOPS to cache at address 4.
                        002B  2093 ;                7. Zero the PC to initiate the instruction prefetch that
                        002B  2094 ;                   writes XB0 and XB1 from cache.
                        002B  2095 ;                8. Execute an IRD1TEST cycle to decode the NOP in XB0.
                        002B  2096 ;                   This will prepare an FPA to be enabled or disabled.
                        002B  2097 ;                9. Halt.
                        002B  2098 ;        3. Execute the following microcode to test for an FPA presence:
                        002B  2099 ;               10. NOP to get the CPU up to speed.
                        002B  2100 ;               11. BUT/NO.FPA,NEXT/1800
                        002B  2101 ;               12. STOP.CLOCK to halt.
                        002B  2102 ;        4. Perform a masked comparison of the address in the Control Store
                        002B  2103 ;           Address Trace Register (CSTRP) against the expected address for the
                        002B  2104 ;           FPA not present.
                        002B  2105 ;        5. If the two do not match, then there is an FPA so branch to
                        002B  2106 ;           Subtest 2. Otherwise continue on to Subtest 1.
                        002B  2107 ;
                        002B  2108 ;       Subtest 1
                        002B  2109 ;
                        002B  2110 ;        6. Loop on error from here.
                        002B  2111 ;        7. Re-execute the microcode in step 3 to test the FPA enable bit.
                        002B  2112 ;        8. Perform a masked comparison of the CSTRP with the expected address
                        002B  2113 ;           for the FPA disabled.
                        002B  2114 ;        9. If the two do not match then there is a problem with the FPA/CPU
                        002B  2115 ;           interface so signal an error.
                        002B  2116 ;       10. Prepare the RDM to expect non-DCS addresses.
                        002B  2117 ;       11. Prepare a loop on I for 256 VAX opcodes.
                        002B  2118 ;       12. Save the loop counter minus one in the RDM memory.
                        002B  2119 ;       13. Load the WDREG with the number saved in RDM memory.
```

```
002B  2120 ;       14. Loop on error from here.
002B  2121 ;       15. Execute the following test microcode:
002B  2122 ;                13. NOP to get the CPU up to speed.
002B  2123 ;                14. Load the opcode to be tested from the WDREG to RTEMP1.
002B  2124 ;                15. Load the operands into the longlit register.
002B  2125 ;                16. Move the operands from the longlit register into the
002B  2126 ;                    Q register.
002B  2127 ;                17. Form the test instruction by ORing the opcode in RTEMP1
002B  2128 ;                    (MTEMP1=RTEMP1) with the operands in the Q register and
002B  2129 ;                    write the result back to RTEMP1.
002B  2130 ;                18. Zero the VA.
002B  2131 ;                19. Write the test instruction in RTEMP1 to cache at address 0.
002B  2132 ;                20. Increment the VA by 4.
002B  2133 ;                21. Validate the next location for XB1 prefetch by writing
002B  2134 ;                    zeros to cache at address 4.
002B  2135 ;                22. Zero the PC to initiate the instruction prefetch that
002B  2136 ;                    writes XB0 and XB1 from cache.
002B  2137 ;                23. Write the contents of XB0 to RTEMP0. This will cause the
002B  2138 ;                    PC to increment by 4 and can change the contents of XB0.
002B  2139 ;                24. Rezero the PC to reload XB0 and XB1.
002B  2140 ;                25. Execute a BUT/IRD1 to decode the instruction in XB0 and
002B  2141 ;                    strobe the VBUS.
002B  2142 ;                26. Halt.
002B  2143 ;       16. Compare the VBUS bit 1E (LOAD OSR L) with the expected value.
002B  2144 ;       17. If the two are not equal, signal an error.
002B  2145 ;       18. Continue to loop on I for the remaining VAX opcodes.
002B  2146 ;       19. Skip to the next test.
002B  2147 ;
002B  2148 ;       Subtests 2 and 3
002B  2149 ;
002B  2150 ;       20. Load the WDREG with a longword to perform an FPA disable for
002B  2151 ;           Subtest 2 or an FPA enable for Subtest 3.
002B  2152 ;       21. Loop on error from here.
002B  2153 ;       22. Execute the following microcode to disable the FPA for Subtest 2 or
002B  2154 ;           to enable the FPA for Subtest 3 and to also check the result:
002B  2155 ;                26. NOP to get the CPU up to speed.
002B  2156 ;                27. WCTRL/FPAENABLE_WB5,WB_RDM to write the FPA's enable bit
002B  2157 ;                    with bit 5 of the RDM's WDREG.
002B  2158 ;                28. NOP
002B  2159 ;                29. BUT/NO.FPA,NEXT/1800 to test for FPA enabled.
002B  2160 ;                30. STOP.CLOCK to halt.
002B  2161 ;       23. Perform a masked comparison of the CSTRP with the expected address
002B  2162 ;           for the FPA disabled (Subtest 2) or the FPA enabled (Subtest 3).
002B  2163 ;       24. If the two do not match then there is a problem with the FPA/CPU
002B  2164 ;           interface so signal an error.
002B  2165 ;       25. Prepare the RDM to expect non-DCS addresses.
002B  2166 ;       26. Prepare a loop on I for 256 VAX opcodes.
002B  2167 ;       27. Save the loop counter minus one in the RDM memory.
002B  2168 ;       28. Load the WDREG with the number saved in RDM memory.
002B  2169 ;       29. Loop on error from here.
002B  2170 ;       30. Execute the same test microcode as in Subtest 1 step 15.
002B  2171 ;       31. Compare the VBUS bit 1E (LOAD OSR L) with the expected value.
002B  2172 ;       32. If the two are not equal, signal an error.
002B  2173 ;       33. Continue to loop on I for the remaining VAX opcodes.
002B  2174 ;       34. If this is Subtest 2 then continue on to Subtest 3.
```

```
                        002B  2175 ;           If this is Subtest 3 then skip to the next test.
                        002B  2176 ;
                        002B  2177 ; TEST PATTERNS
                        002B  2178 ;
                        002B  2179 ;       For this test the VAX machine opcodes are generated by a simple count
                        002B  2180 ;       pattern. The opcodes are based on the 256 base machine instructions
                        002B  2181 ;       as specified in the VAX architecture handbook. The generated opcodes
                        002B  2182 ;       are written to the CPU and combined with three bytes of operand
                        002B  2183 ;       data to form a VAX machine instruction. The operands all specify R0 in
                        002B  2184 ;       register mode and are loaded from the CPU's long literal register.
                        002B  2185 ;
                        002B  2186 ;       Also required are two tables of expected VBUS values in bit 1E for
                        002B  2187 ;       each IRD1 Instruction Decode Cycle. One table contains the expected
                        002B  2188 ;       VBUS data for an IRD1 when the FPA has been disabled, the other for
                        002B  2189 ;       when it is enabled.  The expected VBUS data was obtained from the
                        002B  2190 ;       Native Mode Ird Rom Definition  in the CPU microcode.
                        002B  2191 ;
                        002B  2192 ; LOGIC DESCRIPTION
                        002B  2193 ;
                        002B  2194 ;       The CCS ROMS are fed addresses from ROMS on the DPM during instruction
                        002B  2195 ;       decode. The DPM ROMS are addressed by bits <07:00> of the execution
                        002B  2196 ;       buffer. These bits form the opcode for the instruction. For zero and
                        002B  2197 ;       certain single operand instructions the addresses generated by the ROMS
                        002B  2198 ;       will force a jump to execution flows in the microcode. For the rest,
                        002B  2199 ;       operand specifier evaulation addresses will be generated.
                        002B  2200 ;

                        002B  3508 ;       This test is implemented in three subtests. The first subtest examines
                        002B  3509 ;       the IRD1 ROMS when the CPU's Floating Point Accelerator (FPA) is not
                        002B  3510 ;       present. The second subtest examines the ROMS when there is an FPA
                        002B  3511 ;       present and it has been disabled. The third subtest examines the ROMS
                        002B  3512 ;       when the FPA is present and enabled. The test algorithm executes as
                        002B  3513 ;       follows:
                        002B  3514 ;
                        002B  3515 ;        1. Initialize the CPU. This will clear the FPD bit in the PSL.
                        002B  3516 ;        2. Execute the following microcode to set the FPD bit in the PSL and
                        002B  3517 ;           to prepare an FPA to be enabled or disabled:
                        002B  3518 ;                1. NOP to get the CPU up to speed.
                        002B  3519 ;                2. Load the data needed to set the FPD bit into longlit.
                        002B  3520 ;                3. Set the FPD bit in the PSL.
                        002B  3521 ;                4. Load four NOP opcodes into the longlit register for XB0.
                        002B  3522 ;                5. Zero the VA.
                        002B  3523 ;                6. Write the NOPS for XB0 into cache at address 0.
                        002B  3524 ;                7. Increment the VA by 4.
                        002B  3525 ;                8. Validate the next location for XB1 prefetch by writing
                        002B  3526 ;                   NOPS to cache at address 4.
                        002B  3527 ;                9. Zero the PC to initiate the instruction prefetch that
                        002B  3528 ;                   writes XB0 and XB1 from cache.
                        002B  3529 ;               10. Execute an IRD1TEST cycle to decode the NOP in XB0. This
                        002B  3530 ;                   will intialize the FPA to allow it to be enabled/disabled.
                        002B  3531 ;               11. STOP.CLOCK to halt.
                        002B  3532 ;        3. Execute the following microcode to test for an FPA presence:
                        002B  3533 ;                12. NOP to get the CPU up to speed.
                        002B  3534 ;                13. BUT/NO.FPA,NEXT/1800
                        002B  3535 ;                14. STOP.CLOCK to halt.
                        002B  3536 ;        4. Perform a masked comparison of the address in the Control Store
                        002B  3537 ;           Address Trace Register (CSTRP) against the expected address for the
                        002B  3538 ;           FPA not present.
                        002B  3539 ;        5. If the two do not match, then there is an FPA, so branch to
                        002B  3540 ;           Subtest 2, otherwise continue on to Subtest 1.
                        002B  3541 ;
                        002B  3542 ;       Subtest 1
                        002B  3543 ;
                        002B  3544 ;        6. Loop on error from here.
                        002B  3545 ;        7. Re-execute the microcode in step 3 to test the FPA enable bit.
                        002B  3546 ;        8. Perform a masked comparison of the CSTRP with the expected address
                        002B  3547 ;           for the FPA disabled.
                        002B  3548 ;        9. If the two do not match then there is a problem with the FPA/CPU
                        002B  3549 ;           interface so signal an error.
                        002B  3550 ;       10. Prepare the RDM to expect non-DCS addresses.
                        002B  3551 ;       11. Prepare a loop on I for 256 VAX opcodes.
```

```
002B  3552 ;       12. Save the loop counter minus one in the RDM memory.
002B  3553 ;       13. Load the WDREG with the number saved in RDM memory.
002B  3554 ;       14. Loop on error from here.
002B  3555 ;       15. Execute the following test microcode:
002B  3556 ;                15. NOP to get the CPU up to speed.
002B  3557 ;                16. Load the opcode to be tested from the WDREG to RTEMP1.
002B  3558 ;                17. Load the operands into the longlit register.
002B  3559 ;                18. Move the operands from the longlit register into the
002B  3560 ;                    Q register.
002B  3561 ;                19. Form the test instruction by ORing the opcode in RTEMP1
002B  3562 ;                    (MTEMP1=RTEMP1) with the operands in the Q register and
002B  3563 ;                    write the result back to RTEMP1.
002B  3564 ;                20. Zero the VA.
002B  3565 ;                21. Write the test instruction in RTEMP1 to cache at address 0.
002B  3566 ;                22. Increment the VA by 4.
002B  3567 ;                23. Validate the next location for XB1 prefetch by writing
002B  3568 ;                    zeros to cache at address 4.
002B  3569 ;                24. Zero the PC to initiate the instruction prefetch that
002B  3570 ;                    writes XB0 and XB1 from cache.
002B  3571 ;                25. Write the contents of XB0 to RTEMP0. This will cause the
002B  3572 ;                    PC to increment by 4 and can change the contents of XB0.
002B  3573 ;                26. Rezero the PC to reload XB0 and XB1.
002B  3574 ;                27. Execute a BUT/IRD1 to decode the instruction in XB0.
002B  3575 ;                28. Halt.
002B  3576 ;       16. Perform a masked comparison of the address in the CSTRP register
002B  3577 ;           with the expected control store address for the IRD1.
002B  3578 ;       17. If the two are not equal, signal an error.
002B  3579 ;       18. Continue to loop on I for the remaining VAX opcodes.
002B  3580 ;       19. Skip to the next test.
002B  3581 ;
002B  3582 ;       Subtests 2 and 3
002B  3583 ;
002B  3584 ;       21. Load the WDREG with a longword to perform an FPA disable for
002B  3585 ;           Subtest 2 or an FPA enable for Subtest 3.
002B  3586 ;       21. Loop on error from here.
002B  3587 ;       22. Execute the following microcode to disable the FPA for Subtest 2 or
002B  3588 ;           to enable the FPA for Subtest 3 and to also check the result:
002B  3589 ;                29. NOP to get the CPU up to speed.
002B  3590 ;                30. WCTRL/FPAENABLE_WB5,WB_RDM to write the FPA's enable bit
002B  3591 ;                    with bit 5 of the RDM's WDREG.
002B  3592 ;                31. NOP
002B  3593 ;                32. BUT/NO.FPA,NEXT/1800 to test for FPA enabled.
002B  3594 ;                33. STOP.CLOCK to halt.
002B  3595 ;       23. Perform a masked comparison of the CSTRP with the expected address
002B  3596 ;           for the FPA disabled (Subtest 2) or the FPA enabled (Subtest 3).
002B  3597 ;       24. If the two do not match then there is a problem with the FPA/CPU
002B  3598 ;           interface so signal an error.
002B  3599 ;       25. Prepare the RDM to expect non-DCS addresses.
002B  3600 ;       26. Prepare a loop on I for 256 VAX opcodes.
002B  3601 ;       27. Save the loop counter minus one in the RDM memory.
002B  3602 ;       28. Load the WDREG with the number saved in RDM memory.
002B  3603 ;       29. Loop on error from here.
002B  3604 ;       30. Execute the same test microcode as in Subtest 1 step 15.
002B  3605 ;       31. Perform a masked comparison of the address in the CSTRP register
002B  3606 ;           with the expected control store address for the IRD1.
```

```
                        002B  3607 ;       32. If the two are not equal, signal an error.
                        002B  3608 ;       33. Continue to loop on I for the remaining VAX opcodes.
                        002B  3609 ;       34. If this is Subtest 2 then continue on to Subtest 3.
                        002B  3610 ;           If this is Subtest 3 then skip to the next test.
                        002B  3611 ;
                        002B  3612 ; TEST PATTERNS
                        002B  3613 ;
                        002B  3614 ;       For this test the VAX machine opcodes are generated by a simple count
                        002B  3615 ;       pattern. The opcodes are based on the 256 base machine instructions
                        002B  3616 ;       as specified in the VAX architecture handbook. The generated opcodes
                        002B  3617 ;       are written to the CPU and combined with three bytes of operand
                        002B  3618 ;       data to form a VAX machine instruction. The operands all specify R0 in
                        002B  3619 ;       register mode and are loaded from the CPU's long literal register.
                        002B  3620 ;
                        002B  3621 ;       This test also requires two tables of expected control store addresses
                        002B  3622 ;       for each IRD1 Instruction Decode Cycle. One table contains the expected
                        002B  3623 ;       addresses for an IRD1 when the FPA has been disabled, the other for
                        002B  3624 ;       when it is enabled.  The expected control store addresses were obtained
                        002B  3625 ;       from the Native Mode Ird Rom Definition in the CPU microcode.
                        002B  3626 ;
                        002B  3627 ; LOGIC DESCRIPTION
                        002B  3628 ;
                        002B  3629 ;       The CCS ROMS are fed addresses from ROMS on the DPM during instruction
                        002B  3630 ;       decode. The DPM ROMS are addressed by bits <07:00> of the execution
                        002B  3631 ;       buffer. These bits form the opcode for the instruction. For zero and
                        002B  3632 ;       certain single operand instructions the addresses generated by the ROMS
                        002B  3633 ;       will force a jump to execution flows in the microcode. For the rest,
                        002B  3634 ;       operand specifier evaulation addresses will be generated.
                        002B  3635 ;

                        002B  3992 ;*******************************************************************************
                        002B  3993 ;++
                        002B  3994 ;
                        002B  3995 ; FUNCTIONAL DESCRIPTION
                        002B  3996 ;
                        002B  3997 ;       This test will examine the signal ROM OS INH H in the ROMS that
                        002B  3998 ;       implement a native mode IRD1 when the First Part Done (FPD) bit of the
                        002B  3999 ;       PSL is set to a one.
                        002B  4000 ;
                        002B  4001 ; TEST ALGORITHM
                        002B  4002 ;
                        002B  4003 ;       This test is implemented in three subtests. The first subtest examines
                        002B  4004 ;       the IRD1 ROMS when the CPU's Floating Point Accelerator (FPA) is not
                        002B  4005 ;       present. The second subtest examines the ROMS when there is an FPA
                        002B  4006 ;       present and it has been disabled. The third subtest examines the ROMS
                        002B  4007 ;       when the FPA is present and enabled. The test algorithm executes as
                        002B  4008 ;       follows:
                        002B  4009 ;
                        002B  4010 ;        1. Initialize the CPU. This will clear the FPD bit in the PSL.
                        002B  4011 ;        2. Execute the following microcode to set the FPD bit in the PSL and
                        002B  4012 ;           to prepare an FPA to be enabled or disabled:
                        002B  4013 ;                1. NOP to get the CPU up to speed.
                        002B  4014 ;                2. Load the data needed to set the FPD bit into longlit.
                        002B  4015 ;                3. Set the FPD bit in the PSL.
                        002B  4016 ;                4. Load four NOP opcodes into the longlit register for XB0.
                        002B  4017 ;                5. Zero the VA.
                        002B  4018 ;                6. Write the NOPS for XB0 into cache at address 0.
                        002B  4019 ;                7. Increment the VA by 4.
                        002B  4020 ;                8. Validate the next location for XB1 prefetch by writing
                        002B  4021 ;                   NOPS to cache at address 4.
                        002B  4022 ;                9. Zero the PC to initiate the instruction prefetch that
                        002B  4023 ;                   writes XB0 and XB1 from cache.
                        002B  4024 ;               10. Execute an IRD1TEST cycle to decode the NOP in XB0. This
                        002B  4025 ;                   will intialize the FPA to allow it to be enabled/disabled.
                        002B  4026 ;               11. STOP.CLOCK to halt.
                        002B  4027 ;        3. Execute the following microcode to test for an FPA presence:
                        002B  4028 ;               12. NOP to get the CPU up to speed.
                        002B  4029 ;               13. BUT/NO.FPA,NEXT/1800
                        002B  4030 ;               14. STOP.CLOCK to halt.
                        002B  4031 ;        4. Perform a masked comparison of the address in the Control Store
                        002B  4032 ;           Address Trace Register (CSTRP) against the expected address for the
                        002B  4033 ;           FPA not present.
                        002B  4034 ;        5. If the two do not match, then there is an FPA, so branch to
                        002B  4035 ;           Subtest 2, otherwise continue on to Subtest 1.
                        002B  4036 ;
                        002B  4037 ;       Subtest 1
                        002B  4038 ;
                        002B  4039 ;        6. Loop on error from here.
                        002B  4040 ;        7. Re-execute the microcode in step 3 to test the FPA enable bit.
                        002B  4041 ;        8. Perform a masked comparison of the CSTRP with the expected address
                        002B  4042 ;           for the FPA disabled.
                        002B  4043 ;        9. If the two do not match then there is a problem with the FPA/CPU
                        002B  4044 ;           interface so signal an error.
                        002B  4045 ;       10. Prepare the RDM to expect non-DCS addresses.
```

```
002B  4046 ;       11. Prepare a loop on I for 256 VAX opcodes.
002B  4047 ;       12. Save the loop counter minus one in the RDM memory.
002B  4048 ;       13. Load the WDREG with the number saved in RDM memory.
002B  4049 ;       14. Loop on error from here.
002B  4050 ;       15. Execute the following test microcode:
002B  4051 ;                15. NOP to get the CPU up to speed.
002B  4052 ;                16. Load the opcode to be tested from the WDREG to RTEMP1.
002B  4053 ;                17. Load the operands into the longlit register.
002B  4054 ;                18. Move the operands from the longlit register into the
002B  4055 ;                    Q register.
002B  4056 ;                19. Form the test instruction by ORing the opcode in RTEMP1
002B  4057 ;                    (MTEMP1=RTEMP1) with the operands in the Q register and
002B  4058 ;                    write the result back to RTEMP1.
002B  4059 ;                20. Zero the VA.
002B  4060 ;                21. Write the test instruction in RTEMP1 to cache at address 0.
002B  4061 ;                22. Increment the VA by 4.
002B  4062 ;                23. Validate the next location for XB1 prefetch by writing
002B  4063 ;                    zeros to cache at address 4.
002B  4064 ;                24. Zero the PC to initiate the instruction prefetch that
002B  4065 ;                    writes XB0 and XB1 from cache.
002B  4066 ;                25. Write the contents of XB0 to RTEMP0. This will cause the
002B  4067 ;                    PC to increment by 4 and can change the contents of XB0.
002B  4068 ;                26. Rezero the PC to reload XB0 and XB1.
002B  4069 ;                27. Execute a BUT/IRD1 to decode the instruction in XB0 and
002B  4070 ;                    strobe the VBUS.
002B  4071 ;                28. Halt.
002B  4072 ;       16. Compare the VBUS bit 1E (LOAD OSR L) with the expected value.
002B  4073 ;       17. If the two are not equal, signal an error.
002B  4074 ;       18. Continue to loop on I for the remaining VAX opcodes.
002B  4075 ;       19. Skip to the next test.
002B  4076 ;
002B  4077 ;       Subtests 2 and 3
002B  4078 ;
002B  4079 ;       21. Load the WDREG with a longword to perform an FPA disable for
002B  4080 ;           Subtest 2 or an FPA enable for Subtest 3.
002B  4081 ;       21. Loop on error from here.
002B  4082 ;       22. Execute the following microcode to disable the FPA for Subtest 2 or
002B  4083 ;           to enable the FPA for Subtest 3 and to also check the result:
002B  4084 ;                29. NOP to get the CPU up to speed.
002B  4085 ;                30. WCTRL/FPAENABLE_WB5,WB_RDM to write the FPA's enable bit
002B  4086 ;                    with bit 5 of the RDM's WDREG.
002B  4087 ;                31. NOP
002B  4088 ;                32. BUT/NO.FPA,NEXT/1800 to test for FPA enabled.
002B  4089 ;                33. STOP.CLOCK to halt.
002B  4090 ;       23. Perform a masked comparison of the CSTRP with the expected address
002B  4091 ;           for the FPA disabled (Subtest 2) or the FPA enabled (Subtest 3).
002B  4092 ;       24. If the two do not match then there is a problem with the FPA/CPU
002B  4093 ;           interface so signal an error.
002B  4094 ;       25. Prepare the RDM to expect non-DCS addresses.
002B  4095 ;       26. Prepare a loop on I for 256 VAX opcodes.
002B  4096 ;       27. Save the loop counter minus one in the RDM memory.
002B  4097 ;       28. Load the WDREG with the number saved in RDM memory.
002B  4098 ;       29. Loop on error from here.
002B  4099 ;       30. Execute the same test microcode as in Subtest 1 step 15.
002B  4100 ;       31. Compare the VBUS bit 1E (LOAD OSR L) with the expected value.
```

```
002B  4101 ;       32. If the two are not equal, signal an error.
002B  4102 ;       33. Continue to loop on I for the remaining VAX opcodes.
002B  4103 ;       34. If this is Subtest 2 then continue on to Subtest 3.
002B  4104 ;           If this is Subtest 3 then skip to the next test.
002B  4105 ;
002B  4106 ; TEST PATTERNS
002B  4107 ;
002B  4108 ;       For this test the VAX machine opcodes are generated by a simple count
002B  4109 ;       pattern. The opcodes are based on the 256 base machine instructions
002B  4110 ;       as specified in the VAX architecture handbook. The generated opcodes
002B  4111 ;       are written to the CPU and combined with three bytes of operand
002B  4112 ;       data to form a VAX machine instruction. The operands all specify R0 in
002B  4113 ;       register mode and are loaded from the CPU's long literal register.
002B  4114 ;
002B  4115 ;       Also required are two tables of expected VBUS values in bit 1E for
002B  4116 ;       each IRD1 Instruction Decode Cycle. One table contains the expected
002B  4117 ;       VBUS data for an IRD1 when the FPA has been disabled, the other for
002B  4118 ;       when it is enabled.  The expected VBUS data was obtained from the
002B  4119 ;       Native Mode Ird Rom Definition  in the CPU microcode.
002B  4120 ;
002B  4121 ; LOGIC DESCRIPTION
002B  4122 ;
002B  4123 ;       The CCS ROMS are fed addresses from ROMS on the DPM during instruction
002B  4124 ;       decode. The DPM ROMS are addressed by bits <07:00> of the execution
002B  4125 ;       buffer. These bits form the opcode for the instruction. For zero and
002B  4126 ;       certain single operand instructions the addresses generated by the ROMS
002B  4127 ;       will force a jump to execution flows in the microcode. For the rest,
002B  4128 ;       operand specifier evaulation addresses will be generated.
002B  4129 ;
002B  4130 ; ASSUMPTIONS
002B  4131 ;
002B  4132 ;       This test assumes the following logic has already been tested; the
002B  4133 ;       CPU's data path, the cache, the XB, and the IR and OSR.
002B  4134 ;
002B  4135 ; ERROR DESCRIPTION
002B  4136 ;
002B  4137 ;       On error this test can type out the following information:
002B  4138 ;
002B  4139 ;       Failing gate arrays:    IRD
002B  4140 ;       Failing modules:        FPA, MIC
002B  4141 ;
002B  4142 ;       The following data will also by typed:
002B  4143 ;
002B  4144 ;       Expected VBUS value 00000xnn            where   x  = VBUS bit value
002B  4145 ;       Received VBUS value 00000xnn                    nn = VBUS bit position
002B  4146 ;       Loop count (index I)
002B  4147 ;       The instruction being decoded from XB0 (RTEMP0)
002B  4148 ;
002B  4149 ;--
002B  4150 ;*****************************************************************************

                        0031  5468 ;               b.  Read the WDREG into RTEMP2 (opcode).
                        0031  5469 ;               c.  Load the operands into the LONLIT register.
                        0031  5470 ;               d.  Store the operands into the Q register to prepare for ORing
                        0031  5471 ;                   the opcode with the operands.
                        0031  5472 ;               e.  OR the opcode and operands together (XB0 data).
                        0031  5473 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
                        0031  5474 ;               g.  Zero the VA.
                        0031  5475 ;               h.  Validate cache location 0 by first writing the data in
                        0031  5476 ;                   RTEMP2 then reading the data back.
                        0031  5477 ;               i.  Update the VA by 4.
                        0031  5478 ;               j.  Load the second operand data into the LONLIT register
                        0031  5479 ;                   (XB1 data).
                        0031  5480 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
                        0031  5481 ;               l.  Validate cache location 4 by first writing the data in
                        0031  5482 ;                   the LONLIT register then reading the data back.
                        0031  5483 ;               m.  Load the PC with zero to cause a prefetch to take place.
                        0031  5484 ;               n.  Do an IRD1TST to init the IRD counter and prepare for
                        0031  5485 ;                   instruction/operand specifier evaluation.
                        0031  5486 ;               o.  Halt.
                        0031  5487 ;        9.  Perform the following test microcode.
                        0031  5488 ;               a.  NOP to get the RDM up to speed.
                        0031  5489 ;               b.  Do an IRDX.
```

```
0031  5490 ;                    c.  Halt.
0031  5491 ;          10.  Compare the contents of the CSTRP register (output from the IRDX
0031  5492 ;               Roms) against the Rom Table.
0031  5493 ;          11.  If the two do not equal, execute the following microcode and
0031  5494 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  5495 ;               on the error callout):
0031  5496 ;                  a.  NOP to get the RDM up to speed.
0031  5497 ;                  b.  Load RTEMP0 with the contents of M[TEMP8]
0031  5498 ;                  c.  Load RTEMP1 with the contents of M[TEMP9]
0031  5499 ;                  d.  Halt
0031  5500 ;          12.  Continue with loop I for the 256 VAX opcodes.
0031  5501 ;          13.  Re-enable CTRL/P interrupts then skip to next tests.
0031  5502 ;
0031  5503 ;          Subtest 2
0031  5504 ;
0031  5505 ;          14.  Load the FPA disable bit (bit <5> equal to 0).
0031  5506 ;          15.  Loop on error from here.
0031  5507 ;          16.  Set-up to expect micro trap.
0031  5508 ;          17.  Execute the test microcode.  This is done only to get the FPA to
0031  5509 ;               a state where it can be disabled or enabled.  If this had not been
0031  5510 ;               done before then the FPA would be setting in the initialize state
0031  5511 ;               which forces FPA enable.
0031  5512 ;          18.  Execute the following microcode to disable the FPA:
0031  5513 ;                  a.  NOP to get the RDM up to speed.
0031  5514 ;                  b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  5515 ;                      to the FPA.
0031  5516 ;                  c.  Perform a NO.FPA test to insure that the FPA got disabled.
0031  5517 ;                  d.  Halt.
0031  5518 ;          19.  Check the Trap register to insure that the FPA got disabled.
0031  5519 ;          20.  If the FPA is not disabled, then signal an error.
0031  5520 ;          21.  Set-up flag to expect a micro trap.
0031  5521 ;          22.  Initialize loop I for 256 opcodes (00-FF).
0031  5522 ;          23.  Store the index I in a location that will be used to load into the
0031  5523 ;               WDREG.  The value is used as the opcode.
0031  5524 ;          24.  Loop on error from here.
0031  5525 ;          25.  Execute the following test microcode:
0031  5526 ;                  a.  NOP to get the RDM up to speed.
0031  5527 ;                  b.  Read the WDREG into RTEMP2 (opcode).
0031  5528 ;                  c.  Load the operands into the LONLIT register.
0031  5529 ;                  d.  Store the operands into the Q register to prepare for ORing
0031  5530 ;                      the opcode with the operands.
0031  5531 ;                  e.  OR the opcode and operands together (XB0 data).
0031  5532 ;                  f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  5533 ;                  g.  Zero the VA.
0031  5534 ;                  h.  Validate cache location 0 by first writing the data in
0031  5535 ;                      RTEMP2 then reading the data back.
0031  5536 ;                  i.  Update the VA by 4.
0031  5537 ;                  j.  Load the second operand data into the LONLIT register
0031  5538 ;                      (XB1 data).
0031  5539 ;                  k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  5540 ;                  l.  Validate cache location 4 by first writing the data in
0031  5541 ;                      the LONLIT register then reading the data back.
0031  5542 ;                  m.  Load the PC with zero to cause a prefetch to take place.
0031  5543 ;                  n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031  5544 ;                      tion/operand specifier evaluation.
```

```
0031  5545 ;                   o.  Halt.
0031  5546 ;          26.  Perform the following test microcode.
0031  5547 ;                   a.  NOP to get the RDM up to speed.
0031  5548 ;                   b.  Do an IRDX.
0031  5549 ;                   c.  Halt.
0031  5550 ;          27.  Compare the contents of the CSTRP register (output from the IRDX
0031  5551 ;               Roms) against the Rom Table.
0031  5552 ;          28.  If the two do not equal, execute the following microcode and
0031  5553 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  5554 ;               on the error callout):
0031  5555 ;                   a.  NOP to get the RDM up to speed.
0031  5556 ;                   b.  Load RTEMP0 with the contents of M[TEMP8]
0031  5557 ;                   c.  Load RTEMP1 with the contents of M[TEMP9]
0031  5558 ;                   d.  Halt
0031  5559 ;          29.  Continue with loop I for the 256 VAX opcodes.
0031  5560 ;          30.  Go to Subtest 3.
0031  5561 ;
0031  5562 ;          Subtest 3
0031  5563 ;
0031  5564 ;          31.  Load the FPA enable bit (bit <5> equal to 1).
0031  5565 ;          32.  Loop on error from here.
0031  5566 ;          33.  Set-up to expect micro trap.
0031  5567 ;          34.  Execute the following microcode to enable the FPA:
0031  5568 ;                   a.  NOP to get the RDM up to speed.
0031  5569 ;                   b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  5570 ;                       to the FPA.
0031  5571 ;                   c.  Perform a NO.FPA test to insure that the FPA got enabled.
0031  5572 ;                   d.  Halt.
0031  5573 ;          35.  Check the Trap register to insure that the FPA got enabled.
0031  5574 ;          36.  If the FPA is not enabled, then signal an error.
0031  5575 ;          37.  Set-up flag to expect a micro trap.
0031  5576 ;          38.  Initialize loop I for 256 opcodes (00-FF).
0031  5577 ;          39.  Store the index I in a location that will be used to load into the
0031  5578 ;               WDREG.  The value is used as the opcode.
0031  5579 ;          40.  Loop on error from here.
0031  5580 ;          41.  Set then Clear the DCLO bit in the RDCTRL register to perform an
0031  5581 ;               initialize.  This is done because when the test microcode
0031  5582 ;               executes, if the opcode was an FP opcode then there is a
0031  5583 ;               possibility that the processor could be setting there in an
0031  5584 ;               FPAWAIT state (M clock and D clock stalled).  If this were to
0031  5585 ;               happen then the cpu clocks would no longer run and the remaining
0031  5586 ;               test opcodes would fail.
0031  5587 ;          42.  Execute the following test microcode:
0031  5588 ;                   a.  NOP to get the RDM up to speed.
0031  5589 ;                   b.  Read the WDREG into RTEMP2 (opcode).
0031  5590 ;                   c.  Load the operands into the LONLIT register.
0031  5591 ;                   d.  Store the operands into the Q register to prepare for ORing
0031  5592 ;                       the opcode with the operands.
0031  5593 ;                   e.  OR the opcode and operands together (XB0 data).
0031  5594 ;                   f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  5595 ;                   g.  Zero the VA.
0031  5596 ;                   h.  Validate cache location 0 by first writing the data in
0031  5597 ;                       RTEMP2 then reading the data back.
0031  5598 ;                   i.  Update the VA by 4.
0031  5599 ;                   j.  Load the second operand data into the LONLIT register
```

```
                                                (XB1 data).
                                            k.  Store XB1 data in M[TEMP9] in case needed for error callout.
                                            l.  Validate cache location 4 by first writing the data in
                                                the LONLIT register then reading the data back.
                                            m.  Load the PC with zero to cause a prefetch to take place.
                                            n.  Do an IRD1 to init the IRD counter and prepare for instruc-
                                                tion/operand specifier evaluation.
                                            o.  Halt.
                                    43.  Perform the following test microcode.
                                            a.  NOP to get the RDM up to speed.
                                            b.  Do an IRDX.
                                            c.  Halt.
                                    44.  Compare the contents of the CSTRP register (output from the IRDX
                                    Roms) against the Rom Table.
                                    45.  If the two do not equal, execute the following microcode and
                                    signal an error (this is done to set-up for printing RTEMP0 & 1
                                    on the error callout):
                                            a.  NOP to get the RDM up to speed.
                                            b.  Load RTEMP0 with the contents of M[TEMP8]
                                            c.  Load RTEMP1 with the contents of M[TEMP9]
                                            d.  Halt
                                    46.  Continue with loop I for the 256 VAX opcodes.
                                    47.  Re-enable CTRL/P interrupts.
                                    48.  Skip to next tests.
                                ;
                                ; TEST PATTERNS
                                ;
                                ;       For this test the opcodes are generated by a simple count pattern.  The
                                ;       opcodes are based on the 256 base machine instructions as specified in
                                ;       the VAX architecture handbook.  The generated opcodes are written to
                                ;       the CPU and combined (ORed) with three bytes of operand data to form
                                ;       a machine instruction.  The operands all specify Register Deferred mode
                                ;       using registers 0-6 and are loaded from the LONLIT register.
                                ;
                                ;       Also required are two tables of expected control store addresses for
                                ;       the first IRDX cycle.  One table contains the expected addresses for
                                ;       the first IRDX when the FPA is disabled, the other for when it is
                                ;       enabled.
                                ;
                                ; LOGIC DESCRIPTION
                                ;
                                ;       This test will check the validity of the IRDX roms on the DPM module.
                                ;       The IRDX roms are addressed by bits <7:0> of the Instruction Register.
                                ;       Along with being addressed by the IR, there are three other signals
                                ;       that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
                                ;       REG MODE H.  This test will examine every 8th(hex) address starting at
                                ;       address 2 with FPA disabled and starting at address 0 with FPA enabled.
                                ;

0031  6092 ;*******************************************************************************
0031  6093 ;++
0031  6094 ;
0031  6095 ; FUNCTIONAL DESCRIPTION
0031  6096 ;
0031  6097 ;       This test will examine the signal ROM OS INH H from the Native Mode
0031  6098 ;       IRDX roms when the IRD Counter is equal to zero and the operand
0031  6099 ;       specifier is for a memory reference.
0031  6100 ;
0031  6101 ; TEST ALGORITHM
0031  6102 ;
0031  6103 ;       This test consists of three subtests.  The first subtest will examine
0031  6104 ;       the IRDX roms when the Floating Point Accelerator (FPA) is not present
0031  6105 ;       in the system.  The second subtest will examine the IRDX roms when the
0031  6106 ;       FPA is present but disabled.  The third subtest will examine the IRDX
0031  6107 ;       roms when the FPA is present and enabled.  The algorithm is as follows:
0031  6108 ;
0031  6109 ;        1.  Initialize the processor.
0031  6110 ;        2.  Disable CTRL/P interrupts.
0031  6111 ;        3.  Check to see if FPA present
0031  6112 ;               If FPA present
0031  6113 ;                   Then skip to Subtest 2
0031  6114 ;               Else fall through to Subtest 1
0031  6115 ;
0031  6116 ;       Subtest 1
0031  6117 ;
0031  6118 ;        4.  Set-up flag to expect a micro trap.
0031  6119 ;        5.  Initialize loop I for 256 opcodes (00-FF).
0031  6120 ;        6.  Store the index I in a location that will be used to load into the
0031  6121 ;            WDREG.  The value is used as the opcode.
0031  6122 ;        7.  Loop on error from here.
0031  6123 ;        8.  Execute the following test microcode:
0031  6124 ;               a.  NOP to get the RDM up to speed.
0031  6125 ;               b.  Read the WDREG into RTEMP2 (opcode).
0031  6126 ;               c.  Load the operands into the LONLIT register.
0031  6127 ;               d.  Store the operands into the Q register to prepare for ORing
0031  6128 ;                   the opcode with the operands.
0031  6129 ;               e.  OR the opcode and operands together (XB0 data).
0031  6130 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  6131 ;               g.  Zero the VA.
0031  6132 ;               h.  Validate cache location 0 by first writing the data in
0031  6133 ;                   RTEMP2 then reading the data back.
0031  6134 ;               i.  Update the VA by 4.
0031  6135 ;               j.  Load the second operand data into the LONLIT register
0031  6136 ;                   (XB1 data).
0031  6137 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  6138 ;               l.  Validate cache location 4 by first writing the data in
0031  6139 ;                   the LONLIT register then reading the data back.
0031  6140 ;               m.  Load the PC with zero to cause a prefetch to take place.
0031  6141 ;               n.  Do an IRD1TST to init the IRD counter and prepare for
0031  6142 ;                   instruction/operand specifier evaluation.
0031  6143 ;               o.  Halt.
0031  6144 ;        9.  Perform the following test microcode.
0031  6145 ;               a.  NOP to get the RDM up to speed.
```

```
0031  6146 ;                  b.  Do an IRDX and strobe the VBUS.
0031  6147 ;                  c.  Halt.
0031  6148 ;          10.  Compare the VBUS data with the expected value and bit position
0031  6149 ;               from the VBUS Table.
0031  6150 ;          11.  If the two do not equal, execute the following microcode and
0031  6151 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  6152 ;               on the error callout):
0031  6153 ;                  a.  NOP to get the RDM up to speed.
0031  6154 ;                  b.  Load RTEMP0 with the contents of M[TEMP8]
0031  6155 ;                  c.  Load RTEMP1 with the contents of M[TEMP9]
0031  6156 ;                  d.  Halt
0031  6157 ;          12.  Continue with loop I for the 256 VAX opcodes.
0031  6158 ;          13.  Re-enable CTRL/P interrupts then skip to next tests.
0031  6159 ;
0031  6160 ;          Subtest 2
0031  6161 ;
0031  6162 ;          14.  Load the FPA disable bit (bit <5> equal to 0).
0031  6163 ;          15.  Loop on error from here.
0031  6164 ;          16.  Set-up to expect micro trap.
0031  6165 ;          17.  Execute the test microcode.  This is done only to get the FPA to
0031  6166 ;               a state where it can be disabled or enabled.  If this had not been
0031  6167 ;               done before then the FPA would be setting in the initialize state
0031  6168 ;               which forces FPA enable.
0031  6169 ;          18.  Execute the following microcode to disable the FPA:
0031  6170 ;                  a.  NOP to get the RDM up to speed.
0031  6171 ;                  b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  6172 ;                      to the FPA.
0031  6173 ;                  c.  Perform a NO.FPA test to insure that the FPA got disabled.
0031  6174 ;                  d.  Halt.
0031  6175 ;          19.  Check the Trap register to insure that the FPA got disabled.
0031  6176 ;          20.  If the FPA is not disabled, then signal an error.
0031  6177 ;          21.  Set-up flag to expect a micro trap.
0031  6178 ;          22.  Initialize loop I for 256 opcodes (00-FF).
0031  6179 ;          23.  Store the index I in a location that will be used to load into the
0031  6180 ;               WDREG.  The value is used as the opcode.
0031  6181 ;          24.  Loop on error from here.
0031  6182 ;          25.  Execute the following test microcode:
0031  6183 ;                  a.  NOP to get the RDM up to speed.
0031  6184 ;                  b.  Read the WDREG into RTEMP2 (opcode).
0031  6185 ;                  c.  Load the operands into the LONLIT register.
0031  6186 ;                  d.  Store the operands into the Q register to prepare for ORing
0031  6187 ;                      the opcode with the operands.
0031  6188 ;                  e.  OR the opcode and operands together (XB0 data).
0031  6189 ;                  f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  6190 ;                  g.  Zero the VA.
0031  6191 ;                  h.  Validate cache location 0 by first writing the data in
0031  6192 ;                      RTEMP2 then reading the data back.
0031  6193 ;                  i.  Update the VA by 4.
0031  6194 ;                  j.  Load the second operand data into the LONLIT register
0031  6195 ;                      (XB1 data).
0031  6196 ;                  k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  6197 ;                  l.  Validate cache location 4 by first writing the data in
0031  6198 ;                      the LONLIT register then reading the data back.
0031  6199 ;                  m.  Load the PC with zero to cause a prefetch to take place.
0031  6200 ;                  n.  Do an IRD1 to init the IRD counter and prepare for instruc-
```

```
0031  6201 ;                    tion/operand specifier evaluation.
0031  6202 ;                 o.  Halt.
0031  6203 ;       26.  Perform the following test microcode.
0031  6204 ;                 a.  NOP to get the RDM up to speed.
0031  6205 ;                 b.  Do an IRDX and strobe the VBUS.
0031  6206 ;                 c.  Halt.
0031  6207 ;       27.  Compare the VBUS data with the expected value and bit position
0031  6208 ;            from the VBUS Table.
0031  6209 ;       28.  If the two do not equal, execute the following microcode and
0031  6210 ;            signal an error (this is done to set-up for printing RTEMP0 & 1
0031  6211 ;            on the error callout):
0031  6212 ;                 a.  NOP to get the RDM up to speed.
0031  6213 ;                 b.  Load RTEMP0 with the contents of M[TEMP8]
0031  6214 ;                 c.  Load RTEMP1 with the contents of M[TEMP9]
0031  6215 ;                 d.  Halt
0031  6216 ;       29.  Continue with loop I for the 256 VAX opcodes.
0031  6217 ;       30.  Go to Subtest 3.
0031  6218 ;
0031  6219 ;       Subtest 3
0031  6220 ;
0031  6221 ;       31.  Load the FPA enable bit (bit <5> equal to 1).
0031  6222 ;       32.  Loop on error from here.
0031  6223 ;       33.  Set-up to expect micro trap.
0031  6224 ;       34.  Execute the following microcode to enable the FPA:
0031  6225 ;                 a.  NOP to get the RDM up to speed.
0031  6226 ;                 b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  6227 ;                     to the FPA.
0031  6228 ;                 c.  Perform a NO.FPA test to insure that the FPA got enabled.
0031  6229 ;                 d.  Halt.
0031  6230 ;       35.  Check the Trap register to insure that the FPA got enabled.
0031  6231 ;       36.  If the FPA is not enabled, then signal an error.
0031  6232 ;       37.  Set-up flag to expect a micro trap.
0031  6233 ;       38.  Initialize loop I for 256 opcodes (00-FF).
0031  6234 ;       39.  Store the index I in a location that will be used to load into the
0031  6235 ;            WDREG.  The value is used as the opcode.
0031  6236 ;       40.  Loop on error from here.
0031  6237 ;       41.  Set then Clear the DCLO bit in the RDCTRL register to perform an
0031  6238 ;            initialize.  This is done because when the test microcode
0031  6239 ;            executes, if the opcode was an FP opcode then there is a
0031  6240 ;            possibility that the processor could be setting there in an
0031  6241 ;            FPAWAIT state (M clock and D clock stalled).  If this were to
0031  6242 ;            happen then the cpu clocks would no longer run and the remaining
0031  6243 ;            test opcodes would fail.
0031  6244 ;       42.  Execute the following test microcode:
0031  6245 ;                 a.  NOP to get the RDM up to speed.
0031  6246 ;                 b.  Read the WDREG into RTEMP2 (opcode).
0031  6247 ;                 c.  Load the operands into the LONLIT register.
0031  6248 ;                 d.  Store the operands into the Q register to prepare for ORing
0031  6249 ;                     the opcode with the operands.
0031  6250 ;                 e.  OR the opcode and operands together (XB0 data).
0031  6251 ;                 f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  6252 ;                 g.  Zero the VA.
0031  6253 ;                 h.  Validate cache location 0 by first writing the data in
0031  6254 ;                     RTEMP2 then reading the data back.
0031  6255 ;                 i.  Update the VA by 4.
```

```
0031  6256 ;                  j.  Load the second operand data into the LONLIT register
0031  6257 ;                      (XB1 data).
0031  6258 ;                  k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  6259 ;                  l.  Validate cache location 4 by first writing the data in
0031  6260 ;                      the LONLIT register then reading the data back.
0031  6261 ;                  m.  Load the PC with zero to cause a prefetch to take place.
0031  6262 ;                  n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031  6263 ;                      tion/operand specifier evaluation.
0031  6264 ;                  o.  Halt.
0031  6265 ;          43.  Perform the following test microcode.
0031  6266 ;                  a.  NOP to get the RDM up to speed.
0031  6267 ;                  b.  Do an IRDX and strobe the VBUS.
0031  6268 ;                  c.  Halt.
0031  6269 ;          44.  Compare the VBUS data with the expected value and bit position
0031  6270 ;               from the VBUS Table.
0031  6271 ;          45.  If the two do not equal, execute the following microcode and
0031  6272 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  6273 ;               on the error callout):
0031  6274 ;                  a.  NOP to get the RDM up to speed.
0031  6275 ;                  b.  Load RTEMP0 with the contents of M[TEMP8]
0031  6276 ;                  c.  Load RTEMP1 with the contents of M[TEMP9]
0031  6277 ;                  d.  Halt
0031  6278 ;          46.  Continue with loop I for the 256 VAX opcodes.
0031  6279 ;          47.  Re-enable CTRL/P interrupts.
0031  6280 ;          48.  Skip to next tests.
0031  6281 ;
0031  6282 ; TEST PATTERNS
0031  6283 ;
0031  6284 ;       For this test the opcodes are generated by a simple count pattern.  The
0031  6285 ;       opcodes are based on the 256 base machine instructions as specified in
0031  6286 ;       the VAX architecture handbook.  The generated opcodes are written to
0031  6287 ;       the CPU and combined (ORed) with three bytes of operand data to form
0031  6288 ;       a machine instruction.  The operands all specify Register Deferred mode
0031  6289 ;       using registers 0-6 and are loaded from the LONLIT register.
0031  6290 ;
0031  6291 ;       Also required are two tables of expected VBUS values for the first IRDX
0031  6292 ;       cycle.  One table contains the VBUS values for the first IRDX when the
0031  6293 ;       FPA is disabled, the other for when it is enabled.
0031  6294 ;
0031  6295 ; LOGIC DESCRIPTION
0031  6296 ;
0031  6297 ;       This test will check the validity of the IRDX roms on the DPM module.
0031  6298 ;       The IRDX roms are addressed by bits <7:0> of the Instruction Register.
0031  6299 ;       Along with being addressed by the IR, there are three other signals
0031  6300 ;       that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
0031  6301 ;       REG MODE H.  This test will examine every 8th(hex) address starting at
0031  6302 ;       address 2 with FPA disabled and starting at address 0 with FPA enabled.
0031  6303 ;
0031  6304 ; ASSUMPTIONS
0031  6305 ;
0031  6306 ;       This test assumes the following logic has already been tested; the
0031  6307 ;       CPU's data path, the cache, the XB, and the IR and OSR.
0031  6308 ;

0031  7701 ;*****************************************************************************
0031  7702 ;++
0031  7703 ;
0031  7704 ; FUNCTIONAL DESCRIPTION
0031  7705 ;
0031  7706 ;       This test will examine the Native Mode IRDX roms when the IRD Counter
0031  7707 ;       is equal to zero and the operand specifier is for a register reference.
0031  7708 ;
0031  7709 ; TEST ALGORITHM
0031  7710 ;
0031  7711 ;       This test consists of three subtests.  The first subtest will examine
0031  7712 ;       the IRDX roms when the Floating Point Accelerator (FPA) is not present
0031  7713 ;       in the system.  The second subtest will examine the IRDX roms when the
0031  7714 ;       FPA is present but disabled.  The third subtest will examine the IRDX
0031  7715 ;       roms when the FPA is present and enabled.  The algorithm is as follows:
0031  7716 ;
0031  7717 ;        1.  Initialize the processor.
0031  7718 ;        2.  Disable CTRL/P interrupts.
0031  7719 ;        3.  Check to see if FPA present
0031  7720 ;               If FPA present
0031  7721 ;                   Then skip to Subtest 2
0031  7722 ;               Else fall through to subtest 1
0031  7723 ;
0031  7724 ;       Subtest 1
0031  7725 ;
0031  7726 ;        4.  Set-up flag to expect a micro trap.
0031  7727 ;        5.  Initialize loop I for 256 opcodes (00-FF).
0031  7728 ;        6.  Store the index I in a location that will be used to load into the
0031  7729 ;            WDREG.  The value is used as the opcode.
0031  7730 ;        7.  Loop on error from here.
0031  7731 ;        8.  Execute the following test microcode:
0031  7732 ;               a.  NOP to get the RDM up to speed.
0031  7733 ;               b.  Read the WDREG into RTEMP2 (opcode).
0031  7734 ;               c.  Load the operands into the LONLIT register.
0031  7735 ;               d.  Store the operands into the Q register to prepare for ORing
0031  7736 ;                   the opcode with the operands.
0031  7737 ;               e.  OR the opcode and operands together (XB0 data).
0031  7738 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  7739 ;               g.  Zero the VA.
0031  7740 ;               h.  Validate cache location 0 by first writing the data in
0031  7741 ;                   RTEMP2 then reading the data back.
0031  7742 ;               i.  Update the VA by 4.
0031  7743 ;               j.  Load the second operand data into the LONLIT register
0031  7744 ;                   (XB1 data).
0031  7745 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  7746 ;               l.  Validate cache location 4 by first writing the data in
0031  7747 ;                   the LONLIT register then reading the data back.
0031  7748 ;               m.  Load the PC with zero to cause a prefetch to take place.
0031  7749 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031  7750 ;                   tion/operand specifier evaluation.
0031  7751 ;               o.  Halt.
0031  7752 ;        9.  Perform the following test microcode.
0031  7753 ;               a.  NOP to get the RDM up to speed.
0031  7754 ;               b.  Do an IRDX.
```

```
0031  7755 ;                   c.  Halt.
0031  7756 ;           10.  Compare the contents of the CSTRP register (output from the IRDX
0031  7757 ;                Roms) against the Rom Table.
0031  7758 ;           11.  If the two do not equal, execute the following microcode and
0031  7759 ;                signal an error (this is done to set-up for printing RTEMP0 & 1
0031  7760 ;                on the error callout):
0031  7761 ;                   a.  NOP to get the RDM up to speed.
0031  7762 ;                   b.  Load RTEMP0 with the contents of M[TEMP8]
0031  7763 ;                   c.  Load RTEMP1 with the contents of M[TEMP9]
0031  7764 ;                   d.  Halt
0031  7765 ;           12.  Continue with loop I for the 256 VAX opcodes.
0031  7766 ;           13.  Re-enable CTRL/P interrupts then skip to next tests.
0031  7767 ;
0031  7768 ;           Subtest 2
0031  7769 ;
0031  7770 ;           14.  Load the FPA disable bit (bit <5> equal to 0).
0031  7771 ;           15.  Loop on error from here.
0031  7772 ;           16.  Set-up to expect micro trap.
0031  7773 ;           17.  Execute the test microcode.  This is done only to get the FPA to
0031  7774 ;                a state where it can be disabled or enabled.  If this had not been
0031  7775 ;                done before then the FPA would be setting in the initialize state
0031  7776 ;                which forces FPA enable.
0031  7777 ;           18.  Execute the following microcode to disable the FPA:
0031  7778 ;                   a.  NOP to get the RDM up to speed.
0031  7779 ;                   b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  7780 ;                       to the FPA.
0031  7781 ;                   c.  Perform a NO.FPA test to insure that the FPA got disabled.
0031  7782 ;                   d.  Halt.
0031  7783 ;           19.  Check the Trap register to insure that the FPA got disabled.
0031  7784 ;           20.  If the FPA is not disabled, then signal an error.
0031  7785 ;           21.  Set-up flag to expect a micro trap.
0031  7786 ;           22.  Initialize loop I for 256 opcodes (00-FF).
0031  7787 ;           23.  Store the index I in a location that will be used to load into the
0031  7788 ;                WDREG.  The value is used as the opcode.
0031  7789 ;           24.  Loop on error from here.
0031  7790 ;           25.  Execute the following test microcode:
0031  7791 ;                   a.  NOP to get the RDM up to speed.
0031  7792 ;                   b.  Read the WDREG into RTEMP2 (opcode).
0031  7793 ;                   c.  Load the operands into the LONLIT register.
0031  7794 ;                   d.  Store the operands into the Q register to prepare for ORing
0031  7795 ;                       the opcode with the operands.
0031  7796 ;                   e.  OR the opcode and operands together (XB0 data).
0031  7797 ;                   f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  7798 ;                   g.  Zero the VA.
0031  7799 ;                   h.  Validate cache location 0 by first writing the data in
0031  7800 ;                       RTEMP2 then reading the data back.
0031  7801 ;                   i.  Update the VA by 4.
0031  7802 ;                   j.  Load the second operand data into the LONLIT register
0031  7803 ;                       (XB1 data).
0031  7804 ;                   k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  7805 ;                   l.  Validate cache location 4 by first writing the data in
0031  7806 ;                       the LONLIT register then reading the data back.
0031  7807 ;                   m.  Load the PC with zero to cause a prefetch to take place.
0031  7808 ;                   n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031  7809 ;                       tion/operand specifier evaluation.
```

```
0031  7810 ;                   o.  Halt.
0031  7811 ;           26.  Perform the following test microcode.
0031  7812 ;                   a.  NOP to get the RDM up to speed.
0031  7813 ;                   b.  Do an IRDX.
0031  7814 ;                   c.  Halt.
0031  7815 ;           27.  Compare the contents of the CSTRP register (output from the IRDX
0031  7816 ;                Roms) against the Rom Table.
0031  7817 ;           28.  If the two do not equal, execute the following microcode and
0031  7818 ;                signal an error (this is done to set-up for printing RTEMP0 & 1
0031  7819 ;                on the error callout):
0031  7820 ;                   a.  NOP to get the RDM up to speed.
0031  7821 ;                   b.  Load RTEMP0 with the contents of M[TEMP8]
0031  7822 ;                   c.  Load RTEMP1 with the contents of M[TEMP9]
0031  7823 ;                   d.  Halt
0031  7824 ;           29.  Continue with loop I for the 256 VAX opcodes.
0031  7825 ;           30.  Go to Subtest 3.
0031  7826 ;
0031  7827 ;           Subtest 3
0031  7828 ;
0031  7829 ;           31.  Load the FPA enable bit (bit <5> equal to 1).
0031  7830 ;           32.  Loop on error from here.
0031  7831 ;           33.  Set-up to expect micro trap.
0031  7832 ;           34.  Execute the following microcode to enable the FPA:
0031  7833 ;                   a.  NOP to get the RDM up to speed.
0031  7834 ;                   b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  7835 ;                       to the FPA.
0031  7836 ;                   c.  Perform a NO.FPA test to insure that the FPA got enabled.
0031  7837 ;                   d.  Halt.
0031  7838 ;           35.  Check the Trap register to insure that the FPA got enabled.
0031  7839 ;           36.  If the FPA is not enabled, then signal an error.
0031  7840 ;           37.  Set-up flag to expect a micro trap.
0031  7841 ;           38.  Initialize loop I for 256 opcodes (00-FF).
0031  7842 ;           39.  Store the index I in a location that will be used to load into the
0031  7843 ;                WDREG.  The value is used as the opcode.
0031  7844 ;           40.  Loop on error from here.
0031  7845 ;           41.  Set then Clear the DCLO bit in the RDCTRL register to perform an
0031  7846 ;                initialize.  This is done because when the test microcode
0031  7847 ;                executes, if the opcode was an FP opcode then there is a
0031  7848 ;                possibility that the processor could be setting there in an
0031  7849 ;                FPAWAIT state (M clock and D clock stalled).  If this were to
0031  7850 ;                happen then the cpu clocks would no longer run and the remaining
0031  7851 ;                test opcodes would fail.
0031  7852 ;           42.  Execute the following test microcode:
0031  7853 ;                   a.  NOP to get the RDM up to speed.
0031  7854 ;                   b.  Read the WDREG into RTEMP2 (opcode).
0031  7855 ;                   c.  Load the operands into the LONLIT register.
0031  7856 ;                   d.  Store the operands into the Q register to prepare for ORing
0031  7857 ;                       the opcode with the operands.
0031  7858 ;                   e.  OR the opcode and operands together (XB0 data).
0031  7859 ;                   f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  7860 ;                   g.  Zero the VA.
0031  7861 ;                   h.  Validate cache location 0 by first writing the data in
0031  7862 ;                       RTEMP2 then reading the data back.
0031  7863 ;                   i.  Update the VA by 4.
0031  7864 ;                   j.  Load the second operand data into the LONLIT register
```

```
0031  7865 ;                    (XB1 data).
0031  7866 ;                k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  7867 ;                l.  Validate cache location 4 by first writing the data in
0031  7868 ;                    the LONLIT register then reading the data back.
0031  7869 ;                m.  Load the PC with zero to cause a prefetch to take place.
0031  7870 ;                n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031  7871 ;                    tion/operand specifier evaluation.
0031  7872 ;                o.  Halt.
0031  7873 ;           43.  Perform the following test microcode.
0031  7874 ;                a.  NOP to get the RDM up to speed.
0031  7875 ;                b.  Do an IRDX.
0031  7876 ;                c.  Halt.
0031  7877 ;           44.  Compare the contents of the CSTRP register (output from the IRDX
0031  7878 ;                Roms) against the Rom Table.
0031  7879 ;           45.  If the two do not equal, execute the following microcode and
0031  7880 ;                signal an error (this is done to set-up for printing RTEMP0 & 1
0031  7881 ;                on the error callout):
0031  7882 ;                a.  NOP to get the RDM up to speed.
0031  7883 ;                b.  Load RTEMP0 with the contents of M[TEMP8]
0031  7884 ;                c.  Load RTEMP1 with the contents of M[TEMP9]
0031  7885 ;                d.  Halt
0031  7886 ;           46.  Continue with loop I for the 256 VAX opcodes.
0031  7887 ;           47.  Re-enable CTRL/P interrupts.
0031  7888 ;           48.  Skip to next tests.
0031  7889 ;
0031  7890 ; TEST PATTERNS
0031  7891 ;
0031  7892 ;           For this test the opcodes are generated by a simple count pattern.  The
0031  7893 ;           opcodes are based on the 256 base machine instructions as specified in
0031  7894 ;           the VAX architecture handbook.  The generated opcodes are written to
0031  7895 ;           the CPU and combined (ORed) with three bytes of operand data to form
0031  7896 ;           a machine instruction.  The operands all specify Register mode using
0031  7897 ;           registers 0-6 and are loaded from the LONLIT register.
0031  7898 ;
0031  7899 ;           Also required are two tables of expected control store addresses for
0031  7900 ;           the first IRDX cycle.  One table contains the expected addresses for
0031  7901 ;           the first IRDX when the FPA is disabled, the other for when it is
0031  7902 ;           enabled.
0031  7903 ;
0031  7904 ; LOGIC DESCRIPTION
0031  7905 ;
0031  7906 ;           This test will check the validity of the IRDX roms on the DPM module.
0031  7907 ;           The IRDX roms are addressed by bits <7:0> of the Instruction Register.
0031  7908 ;           Along with being addressed by the IR, there are three other signals
0031  7909 ;           that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
0031  7910 ;           REG MODE H.  This test will examine every 8th(hex) address starting at
0031  7911 ;           address 3 with FPA disabled and starting at address 1 with FPA enabled.
0031  7912 ;
0031  7913 ; ASSUMPTIONS
0031  7914 ;
0031  7915 ;           This test assumes the following logic has already been tested; the
0031  7916 ;           CPU's data path, the cache, the XB, and the IR and OSR.
0031  7917 ;

0031   8357 ;*****************************************************************************
0031   8358 ;++
0031   8359 ;
0031   8360 ; FUNCTIONAL DESCRIPTION
0031   8361 ;
0031   8362 ;       This test will examine the signal ROM OS INH H from the Native Mode
0031   8363 ;       IRDX roms when the IRD Counter is equal to zero and the operand
0031   8364 ;       specifier is for a register reference.
0031   8365 ;
0031   8366 ; TEST ALGORITHM
0031   8367 ;
0031   8368 ;       This test consists of three subtests.  The first subtest will examine
0031   8369 ;       the IRDX roms when the Floating Point Accelerator (FPA) is not present
0031   8370 ;       in the system.  The second subtest will examine the IRDX roms when the
0031   8371 ;       FPA is present but disabled.  The third subtest will examine the IRDX
0031   8372 ;       roms when the FPA is present and enabled.  The algorithm is as follows:
0031   8373 ;
0031   8374 ;        1.  Initialize the processor.
0031   8375 ;        2.  Disable CTRL/P interrupts.
0031   8376 ;        3.  Check to see if FPA present
0031   8377 ;               If FPA present
0031   8378 ;                   Then skip to Subtest 2
0031   8379 ;               Else fall through to subtest 1
0031   8380 ;
0031   8381 ;       Subtest 1
0031   8382 ;
0031   8383 ;        4.  Set-up flag to expect a micro trap.
0031   8384 ;        5.  Initialize loop I for 256 opcodes (00-FF).
0031   8385 ;        6.  Store the index I in a location that will be used to load into the
0031   8386 ;            WDREG.  The value is used as the opcode.
0031   8387 ;        7.  Loop on error from here.
0031   8388 ;        8.  Execute the following test microcode:
0031   8389 ;               a.  NOP to get the RDM up to speed.
0031   8390 ;               b.  Read the WDREG into RTEMP2 (opcode).
0031   8391 ;               c.  Load the operands into the LONLIT register.
0031   8392 ;               d.  Store the operands into the Q register to prepare for ORing
0031   8393 ;                   the opcode with the operands.
0031   8394 ;               e.  OR the opcode and operands together (XB0 data).
0031   8395 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031   8396 ;               g.  Zero the VA.
0031   8397 ;               h.  Validate cache location 0 by first writing the data in
0031   8398 ;                   RTEMP2 then reading the data back.
0031   8399 ;               i.  Update the VA by 4.
0031   8400 ;               j.  Load the second operand data into the LONLIT register
0031   8401 ;                   (XB1 data).
0031   8402 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031   8403 ;               l.  Validate cache location 4 by first writing the data in
0031   8404 ;                   the LONLIT register then reading the data back.
0031   8405 ;               m.  Load the PC with zero to cause a prefetch to take place.
0031   8406 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031   8407 ;                   tion/operand specifier evaluation.
0031   8408 ;               o.  Halt.
0031   8409 ;        9.  Perform the following test microcode.
0031   8410 ;               a.  NOP to get the RDM up to speed.
```

```
0031  8411 ;                  b.  Do an IRDX and strobe the VBUS.
0031  8412 ;                  c.  Halt.
0031  8413 ;          10.  Compare the VBUS data with the expected value and bit position
0031  8414 ;               from the VBUS Table.
0031  8415 ;          11.  If the two do not equal, execute the following microcode and
0031  8416 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  8417 ;               on the error callout):
0031  8418 ;                  a.  NOP to get the RDM up to speed.
0031  8419 ;                  b.  Load RTEMP0 with the contents of M[TEMP8]
0031  8420 ;                  c.  Load RTEMP1 with the contents of M[TEMP9]
0031  8421 ;                  d.  Halt
0031  8422 ;          12.  Continue with loop I for the 256 VAX opcodes.
0031  8423 ;          13.  Re-enable CTRL/P interrupts then skip to next tests.
0031  8424 ;
0031  8425 ;          Subtest 2
0031  8426 ;
0031  8427 ;          14.  Load the FPA disable bit (bit <5> equal to 0).
0031  8428 ;          15.  Loop on error from here.
0031  8429 ;          16.  Set-up to expect micro trap.
0031  8430 ;          17.  Execute the test microcode.  This is done only to get the FPA to
0031  8431 ;               a state where it can be disabled or enabled.  If this had not been
0031  8432 ;               done before then the FPA would be setting in the initialize state
0031  8433 ;               which forces FPA enable.
0031  8434 ;          18.  Execute the following microcode to disable the FPA:
0031  8435 ;                  a.  NOP to get the RDM up to speed.
0031  8436 ;                  b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  8437 ;                      to the FPA.
0031  8438 ;                  c.  Perform a NO.FPA test to insure that the FPA got disabled.
0031  8439 ;                  d.  Halt.
0031  8440 ;          19.  Check the Trap register to insure that the FPA got disabled.
0031  8441 ;          20.  If the FPA is not disabled, then signal an error.
0031  8442 ;          21.  Set-up flag to expect a micro trap.
0031  8443 ;          22.  Initialize loop I for 256 opcodes (00-FF).
0031  8444 ;          23.  Store the index I in a location that will be used to load into the
0031  8445 ;               WDREG.  The value is used as the opcode.
0031  8446 ;          24.  Loop on error from here.
0031  8447 ;          25.  Execute the following test microcode:
0031  8448 ;                  a.  NOP to get the RDM up to speed.
0031  8449 ;                  b.  Read the WDREG into RTEMP2 (opcode).
0031  8450 ;                  c.  Load the operands into the LONLIT register.
0031  8451 ;                  d.  Store the operands into the Q register to prepare for ORing
0031  8452 ;                      the opcode with the operands.
0031  8453 ;                  e.  OR the opcode and operands together (XB0 data).
0031  8454 ;                  f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  8455 ;                  g.  Zero the VA.
0031  8456 ;                  h.  Validate cache location 0 by first writing the data in
0031  8457 ;                      RTEMP2 then reading the data back.
0031  8458 ;                  i.  Update the VA by 4.
0031  8459 ;                  j.  Load the second operand data into the LONLIT register
0031  8460 ;                      (XB1 data).
0031  8461 ;                  k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  8462 ;                  l.  Validate cache location 4 by first writing the data in
0031  8463 ;                      the LONLIT register then reading the data back.
0031  8464 ;                  m.  Load the PC with zero to cause a prefetch to take place.
0031  8465 ;                  n.  Do an IRD1 to init the IRD counter and prepare for instruc-
```

```
0031  8466 ;                    tion/operand specifier evaluation.
0031  8467 ;                 o.  Halt.
0031  8468 ;          26.  Perform the following test microcode.
0031  8469 ;                 a.  NOP to get the RDM up to speed.
0031  8470 ;                 b.  Do an IRDX and strobe the VBUS.
0031  8471 ;                 c.  Halt.
0031  8472 ;          27.  Compare the VBUS data with the expected value and bit position
0031  8473 ;               from the VBUS Table.
0031  8474 ;          28.  If the two do not equal, execute the following microcode and
0031  8475 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  8476 ;               on the error callout):
0031  8477 ;                 a.  NOP to get the RDM up to speed.
0031  8478 ;                 b.  Load RTEMP0 with the contents of M[TEMP8]
0031  8479 ;                 c.  Load RTEMP1 with the contents of M[TEMP9]
0031  8480 ;                 d.  Halt
0031  8481 ;          29.  Continue with loop I for the 256 VAX opcodes.
0031  8482 ;          30.  Go to Subtest 3.
0031  8483 ;
0031  8484 ;          Subtest 3
0031  8485 ;
0031  8486 ;          31.  Load the FPA enable bit (bit <5> equal to 1).
0031  8487 ;          32.  Loop on error from here.
0031  8488 ;          33.  Set-up to expect micro trap.
0031  8489 ;          34.  Execute the following microcode to enable the FPA:
0031  8490 ;                 a.  NOP to get the RDM up to speed.
0031  8491 ;                 b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0031  8492 ;                     to the FPA.
0031  8493 ;                 c.  Perform a NO.FPA test to insure that the FPA got enabled.
0031  8494 ;                 d.  Halt.
0031  8495 ;          35.  Check the Trap register to insure that the FPA got enabled.
0031  8496 ;          36.  If the FPA is not enabled, then signal an error.
0031  8497 ;          37.  Set-up flag to expect a micro trap.
0031  8498 ;          38.  Initialize loop I for 256 opcodes (00-FF).
0031  8499 ;          39.  Store the index I in a location that will be used to load into the
0031  8500 ;               WDREG.  The value is used as the opcode.
0031  8501 ;          40.  Loop on error from here.
0031  8502 ;          41.  Set then Clear the DCLO bit in the RDCTRL register to perform an
0031  8503 ;               initialize.  This is done because when the test microcode
0031  8504 ;               executes, if the opcode was an FP opcode then there is a
0031  8505 ;               possibility that the processor could be setting there in an
0031  8506 ;               FPAWAIT state (M clock and D clock stalled).  If this were to
0031  8507 ;               happen then the cpu clocks would no longer run and the remaining
0031  8508 ;               test opcodes would fail.
0031  8509 ;          42.  Execute the following test microcode:
0031  8510 ;                 a.  NOP to get the RDM up to speed.
0031  8511 ;                 b.  Read the WDREG into RTEMP2 (opcode).
0031  8512 ;                 c.  Load the operands into the LONLIT register.
0031  8513 ;                 d.  Store the operands into the Q register to prepare for ORing
0031  8514 ;                     the opcode with the operands.
0031  8515 ;                 e.  OR the opcode and operands together (XB0 data).
0031  8516 ;                 f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0031  8517 ;                 g.  Zero the VA.
0031  8518 ;                 h.  Validate cache location 0 by first writing the data in
0031  8519 ;                     RTEMP2 then reading the data back.
0031  8520 ;                 i.  Update the VA by 4.
```

```
0031  8521 ;                  j.  Load the second operand data into the LONLIT register
0031  8522 ;                      (XB1 data).
0031  8523 ;                  k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0031  8524 ;                  l.  Validate cache location 4 by first writing the data in
0031  8525 ;                      the LONLIT register then reading the data back.
0031  8526 ;                  m.  Load the PC with zero to cause a prefetch to take place.
0031  8527 ;                  n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0031  8528 ;                      tion/operand specifier evaluation.
0031  8529 ;                  o.  Halt.
0031  8530 ;          43.  Perform the following test microcode.
0031  8531 ;                  a.  NOP to get the RDM up to speed.
0031  8532 ;                  b.  Do an IRDX and strobe the VBUS.
0031  8533 ;                  c.  Halt.
0031  8534 ;          44.  Compare the VBUS data with the expected value and bit position
0031  8535 ;               from the VBUS Table.
0031  8536 ;          45.  If the two do not equal, execute the following microcode and
0031  8537 ;               signal an error (this is done to set-up for printing RTEMP0 & 1
0031  8538 ;               on the error callout):
0031  8539 ;                  a.  NOP to get the RDM up to speed.
0031  8540 ;                  b.  Load RTEMP0 with the contents of M[TEMP8]
0031  8541 ;                  c.  Load RTEMP1 with the contents of M[TEMP9]
0031  8542 ;                  d.  Halt
0031  8543 ;          46.  Continue with loop I for the 256 VAX opcodes.
0031  8544 ;          47.  Re-enable CTRL/P interrupts.
0031  8545 ;          48.  Skip to next tests.
0031  8546 ;
0031  8547 ; TEST PATTERNS
0031  8548 ;
0031  8549 ;          For this test the opcodes are generated by a simple count pattern.  The
0031  8550 ;          opcodes are based on the 256 base machine instructions as specified in
0031  8551 ;          the VAX architecture handbook.  The generated opcodes are written to
0031  8552 ;          the CPU and combined (ORed) with three bytes of operand data to form
0031  8553 ;          a machine instruction.  The operands all specify Register mode using
0031  8554 ;          registers 0-6 and are loaded from the LONLIT register.
0031  8555 ;
0031  8556 ;          Also required are two tables of expected VBUS values for the first IRDX
0031  8557 ;          cycle.  One table contains the VBUS values for the first IRDX when the
0031  8558 ;          FPA is disabled, the other for when it is enabled.
0031  8559 ;
0031  8560 ; LOGIC DESCRIPTION
0031  8561 ;
0031  8562 ;          This test will check the validity of the IRDX roms on the DPM module.
0031  8563 ;          The IRDX roms are addressed by bits <7:0> of the Instruction Register.
0031  8564 ;          Along with being addressed by the IR, there are three other signals
0031  8565 ;          that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
0031  8566 ;          REG MODE H.  This test will examine every 8th(hex) address starting at
0031  8567 ;          address 3 with FPA disabled and starting at address 1 with FPA enabled.
0031  8568 ;
0031  8569 ; ASSUMPTIONS
0031  8570 ;
0031  8571 ;          This test assumes the following logic has already been tested; the
0031  8572 ;          CPU's data path, the cache, the XB, and the IR and OSR.
0031  8573 ;
0031  8574 ; ERROR DESCRIPTION

0032  9966 ;*****************************************************************************
0032  9967 ;++
0032  9968 ;
0032  9969 ; FUNCTIONAL DESCRIPTION
0032  9970 ;
0032  9971 ;       This test will examine the Native Mode IRDX roms when the IRD Counter
0032  9972 ;       is equal to one and the operand specifier is for a memory reference.
0032  9973 ;
0032  9974 ; TEST ALGORITHM
0032  9975 ;
0032  9976 ;       This test consists of three subtests.  The first subtest will examine
0032  9977 ;       the IRDX roms when the Floating Point Accelerator (FPA) is not present
0032  9978 ;       in the system.  The second subtest will examine the IRDX roms when the
0032  9979 ;       FPA is present but disabled.  The third subtest will examine the IRDX
0032  9980 ;       roms when the FPA is present and enabled.  The algorithm is as follows:
0032  9981 ;
0032  9982 ;        1.  Initialize the processor.
0032  9983 ;        2.  Disable CTRL/P interrupts.
0032  9984 ;        3.  Check to see if FPA present
0032  9985 ;               If FPA present
0032  9986 ;                   Then skip to Subtest 2
0032  9987 ;               Else fall through to subtest 1
0032  9988 ;
0032  9989 ;       Subtest 1
0032  9990 ;
0032  9991 ;        4.  Set-up flag to expect a micro trap.
0032  9992 ;        5.  Initialize loop I for 256 opcodes (00-FF).
0032  9993 ;        6.  Store the index I in a location that will be used to load into the
0032  9994 ;            WDREG.  The value is used as the opcode.
0032  9995 ;        7.  Loop on error from here.
0032  9996 ;        8.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032  9997 ;            is used to get the IRD counter to 1 without sourcing an address
0032  9998 ;            from the IRDX roms (ie., by doing an IRDX).
0032  9999 ;        9.  Execute the following test microcode (performs the IRD1):
0032 10000 ;               a.  NOP to get the RDM up to speed.
0032 10001 ;               b.  Read the WDREG into RTEMP2 (opcode).
0032 10002 ;               c.  Load the operands into the LONLIT register.
0032 10003 ;               d.  Store the operands into the Q register to prepare for ORing
0032 10004 ;                   the opcode with the operands.
0032 10005 ;               e.  OR the opcode and operands together (XB0 data).
0032 10006 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 10007 ;               g.  Zero the VA.
0032 10008 ;               h.  Validate cache location 0 by first writing the data in
0032 10009 ;                   RTEMP2 then reading the data back.
0032 10010 ;               i.  Update the VA by 4.
0032 10011 ;               j.  Load the second operand data into the LONLIT register
0032 10012 ;                   (XB1 data).
0032 10013 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0032 10014 ;               l.  Validate cache location 4 by first writing the data in
0032 10015 ;                   the LONLIT register then reading the data back.
0032 10016 ;               m.  Load the PC with zero to cause a prefetch to take place.
0032 10017 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 10018 ;                   tion/operand specifier evaluation.
0032 10019 ;               o.  Halt.
```

```
0032 10020 ;       10.  Perform the following test microcode (performs the LOD.INC.BRA?)
0032 10021 ;              a.  NOP to get the RDM up to speed.
0032 10022 ;              b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 10023 ;              c.  Halt.
0032 10024 ;       11.  Load DCS location 12 with a BUT/IRDX micro order.
0032 10025 ;       12.  Perform the following test microcode (performs the IRDX with the
0032 10026 ;            IRD counter = 1):
0032 10027 ;              a.  NOP to get the RDM up to speed.
0032 10028 ;              b.  Do an IRDX.
0032 10029 ;              c.  Halt.
0032 10030 ;       13.  Compare the contents of the CSTRP register (output from the IRDX
0032 10031 ;            Roms) against the Rom Table.
0032 10032 ;       14.  If the two do not equal, execute the following microcode and
0032 10033 ;            signal an error (this is done to set-up for printing RTEMP0 & 1
0032 10034 ;            on the error callout):
0032 10035 ;              a.  NOP to get the RDM up to speed.
0032 10036 ;              b.  Load RTEMP0 with the contents of M[TEMP8]
0032 10037 ;              c.  Load RTEMP1 with the contents of M[TEMP9]
0032 10038 ;              d.  Halt
0032 10039 ;       15.  Continue with loop I for the 256 VAX opcodes.
0032 10040 ;       16.  Re-enable CTRL/P interrupts then skip to next tests.
0032 10041 ;
0032 10042 ;       Subtest 2
0032 10043 ;
0032 10044 ;       17.  Load the FPA disable bit (bit <5> equal to 0).
0032 10045 ;       18.  Loop on error from here.
0032 10046 ;       19.  Set-up to expect micro trap.
0032 10047 ;       20.  Execute the test microcode.  This is done only to get the FPA to
0032 10048 ;            a state where it can be disabled or enabled.  If this had not been
0032 10049 ;            done before then the FPA would be setting in the initialize state
0032 10050 ;            which forces FPA enable.
0032 10051 ;       21.  Execute the following microcode to disable the FPA:
0032 10052 ;              a.  NOP to get the RDM up to speed.
0032 10053 ;              b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 10054 ;                  to the FPA.
0032 10055 ;              c.  Perform a NO.FPA test to insure that the FPA got disabled.
0032 10056 ;              d.  Halt.
0032 10057 ;       22.  Check the Trap register to insure that the FPA got disabled.
0032 10058 ;       23.  If the FPA is not disabled, then signal an error.
0032 10059 ;       24.  Set-up flag to expect a micro trap.
0032 10060 ;       25.  Initialize loop I for 256 opcodes (00-FF).
0032 10061 ;       26.  Store the index I in a location that will be used to load into the
0032 10062 ;            WDREG.  The value is used as the opcode.
0032 10063 ;       27.  Loop on error from here.
0032 10064 ;       28.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 10065 ;            is used to get the IRD counter to 1 without sourcing an address
0032 10066 ;            from the IRDX roms (ie., by doing an IRDX).
0032 10067 ;       29.  Execute the following test microcode:
0032 10068 ;              a.  NOP to get the RDM up to speed.
0032 10069 ;              b.  Read the WDREG into RTEMP2 (opcode).
0032 10070 ;              c.  Load the operands into the LONLIT register.
0032 10071 ;              d.  Store the operands into the Q register to prepare for ORing
0032 10072 ;                  the opcode with the operands.
0032 10073 ;              e.  OR the opcode and operands together (XB0 data).
0032 10074 ;              f.  Store XB0 data in M[TEMP8] in case needed for error callout.
```

```
0032 10075 ;                    g.  Zero the VA.
0032 10076 ;                    h.  Validate cache location 0 by first writing the data in
0032 10077 ;                        RTEMP2 then reading the data back.
0032 10078 ;                    i.  Update the VA by 4.
0032 10079 ;                    j.  Load the second operand data into the LONLIT register
0032 10080 ;                        (XB1 data).
0032 10081 ;                    k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0032 10082 ;                    l.  Validate cache location 4 by first writing the data in
0032 10083 ;                        the LONLIT register then reading the data back.
0032 10084 ;                    m.  Load the PC with zero to cause a prefetch to take place.
0032 10085 ;                    n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 10086 ;                        tion/operand specifier evaluation.
0032 10087 ;                    o.  Halt.
0032 10088 ;            30.  Perform the following test microcode.
0032 10089 ;                    a.  NOP to get the RDM up to speed.
0032 10090 ;                    b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 10091 ;                    c.  Halt.
0032 10092 ;            31.  Load DCS location 12 with a BUT/IRDX micro order.
0032 10093 ;            32.  Perform the following test microcode (performs the IRDX with the
0032 10094 ;                 IRD counter = 1):
0032 10095 ;                    a.  NOP to get the RDM up to speed.
0032 10096 ;                    b.  Do an IRDX.
0032 10097 ;                    c.  Halt.
0032 10098 ;            33.  Compare the contents of the CSTRP register (output from the IRDX
0032 10099 ;                 Roms) against the Rom Table.
0032 10100 ;            34.  If the two do not equal, execute the following microcode and
0032 10101 ;                 signal an error (this is done to set-up for printing RTEMP0 & 1
0032 10102 ;                 on the error callout):
0032 10103 ;                    a.  NOP to get the RDM up to speed.
0032 10104 ;                    b.  Load RTEMP0 with the contents of M[TEMP8]
0032 10105 ;                    c.  Load RTEMP1 with the contents of M[TEMP9]
0032 10106 ;                    d.  Halt
0032 10107 ;            35.  Continue with loop I for the 256 VAX opcodes.
0032 10108 ;            36.  Go to Subtest 3.
0032 10109 ;
0032 10110 ;            Subtest 3
0032 10111 ;
0032 10112 ;            37.  Load the FPA enable bit (bit <5> equal to 1).
0032 10113 ;            38.  Loop on error from here.
0032 10114 ;            39.  Set-up to expect micro trap.
0032 10115 ;            40.  Execute the following microcode to enable the FPA:
0032 10116 ;                    a.  NOP to get the RDM up to speed.
0032 10117 ;                    b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 10118 ;                        to the FPA.
0032 10119 ;                    c.  Perform a NO.FPA test to insure that the FPA got enabled.
0032 10120 ;                    d.  Halt.
0032 10121 ;            41.  Check the Trap register to insure that the FPA got enabled.
0032 10122 ;            42.  If the FPA is not enabled, then signal an error.
0032 10123 ;            43.  Set-up flag to expect a micro trap.
0032 10124 ;            44.  Initialize loop I for 256 opcodes (00-FF).
0032 10125 ;            45.  Store the index I in a location that will be used to load into the
0032 10126 ;                 WDREG.  The value is used as the opcode.
0032 10127 ;            46.  Loop on error from here.
0032 10128 ;            47.  Set then Clear the DCLO bit in the RDCTRL register to perform an
0032 10129 ;                 initialize.  This is done because when the test microcode
```

```
0032 10130 ;            executes, if the opcode was an FP opcode then there is a
0032 10131 ;            possibility that the processor could be setting there in an
0032 10132 ;            FPAWAIT state (M clock and D clock stalled).  If this were to
0032 10133 ;            happen then the cpu clocks would no longer run and the remaining
0032 10134 ;            test opcodes would fail.
0032 10135 ;       48.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 10136 ;            is used to get the IRD counter to 1 without sourcing an address
0032 10137 ;            from the IRDX roms (ie., by doing an IRDX).
0032 10138 ;       49.  Execute the following test microcode:
0032 10139 ;               a.  NOP to get the RDM up to speed.
0032 10140 ;               b.  Read the WDREG into RTEMP2 (opcode).
0032 10141 ;               c.  Load the operands into the LONLIT register.
0032 10142 ;               d.  Store the operands into the Q register to prepare for ORing
0032 10143 ;                   the opcode with the operands.
0032 10144 ;               e.  OR the opcode and operands together (XB0 data).
0032 10145 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 10146 ;               g.  Zero the VA.
0032 10147 ;               h.  Validate cache location 0 by first writing the data in
0032 10148 ;                   RTEMP2 then reading the data back.
0032 10149 ;               i.  Update the VA by 4.
0032 10150 ;               j.  Load the second operand data into the LONLIT register
0032 10151 ;                   (XB1 data).
0032 10152 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0032 10153 ;               l.  Validate cache location 4 by first writing the data in
0032 10154 ;                   the LONLIT register then reading the data back.
0032 10155 ;               m.  Load the PC with zero to cause a prefetch to take place.
0032 10156 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 10157 ;                   tion/operand specifier evaluation.
0032 10158 ;               o.  Halt.
0032 10159 ;       50.  Perform the following test microcode.
0032 10160 ;               a.  NOP to get the RDM up to speed.
0032 10161 ;               b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 10162 ;               c.  Halt.
0032 10163 ;       51.  Load DCS location 12 with a BUT/IRDX micro order.
0032 10164 ;       52.  Perform the following test microcode (performs the IRDX with the
0032 10165 ;            IRD counter = 1):
0032 10166 ;               a.  NOP to get the RDM up to speed.
0032 10167 ;               b.  Do an IRDX.
0032 10168 ;               c.  Halt.
0032 10169 ;       53.  Compare the contents of the CSTRP register (output from the IRDX
0032 10170 ;            Roms) against the Rom Table.
0032 10171 ;       54.  If the two do not equal, execute the following microcode and
0032 10172 ;            signal an error (this is done to set-up for printing RTEMP0 & 1
0032 10173 ;            on the error callout):
0032 10174 ;               a.  NOP to get the RDM up to speed.
0032 10175 ;               b.  Load RTEMP0 with the contents of M[TEMP8]
0032 10176 ;               c.  Load RTEMP1 with the contents of M[TEMP9]
0032 10177 ;               d.  Halt
0032 10178 ;       55.  Continue with loop I for the 256 VAX opcodes.
0032 10179 ;       56.  Re-enable CTRL/P interrupts.
0032 10180 ;       57.  Skip to next tests.
0032 10181 ;
0032 10182 ; TEST PATTERNS
0032 10183 ;
0032 10184 ;            For this test the opcodes are generated by a simple count pattern.  The
```

```
0032 10185 ;       opcodes are based on the 256 base machine instructions as specified in
0032 10186 ;       the VAX architecture handbook.  The generated opcodes are written to
0032 10187 ;       the CPU and combined (ORed) with three bytes of operand data to form
0032 10188 ;       a machine instruction.  The operands all specify Register Deferred mode
0032 10189 ;       using registers 0-6 and are loaded from the LONLIT register.
0032 10190 ;
0032 10191 ;       Also required are two tables of expected control store addresses for
0032 10192 ;       the second IRDX cycle.  One table contains the expected addresses for
0032 10193 ;       the second IRDX when the FPA is disabled, the other for when it is
0032 10194 ;       enabled.
0032 10195 ;
0032 10196 ; LOGIC DESCRIPTION
0032 10197 ;
0032 10198 ;       This test will check the validity of the IRDX roms on the DPM module.
0032 10199 ;       The IRDX roms are addressed by bits <7:0> of the Instruction Register.
0032 10200 ;       Along with being addressed by the IR, there are three other signals
0032 10201 ;       that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
0032 10202 ;       REG MODE H.  This test will examine every 8th(hex) address starting at
0032 10203 ;       address 6 with FPA disabled and starting at address 4 with FPA enabled.
0032 10204 ;
0032 10205 ; ASSUMPTIONS
0032 10206 ;
0032 10207 ;       This test assumes the following logic has already been tested; the
0032 10208 ;       CPU's data path, the cache, the XB, and the IR and OSR.
0032 10209 ;

                        0032 10673 ;       This test consists of three subtests.  The first subtest will examine
                        0032 10674 ;       the IRDX roms when the Floating Point Accelerator (FPA) is not present
                        0032 10675 ;       in the system.  The second subtest will examine the IRDX roms when the
                        0032 10676 ;       FPA is present but disabled.  The third subtest will examine the IRDX
                        0032 10677 ;       roms when the FPA is present and enabled.  The algorithm is as follows:
                        0032 10678 ;
                        0032 10679 ;        1.  Initialize the processor.
                        0032 10680 ;        2.  Disable CTRL/P interrupts.
                        0032 10681 ;        3.  Check to see if FPA present
                        0032 10682 ;               If FPA present
                        0032 10683 ;                   Then skip to Subtest 2
                        0032 10684 ;               Else fall through to subtest 1
                        0032 10685 ;
                        0032 10686 ;       Subtest 1
                        0032 10687 ;
                        0032 10688 ;        4.  Set-up flag to expect a micro trap.
                        0032 10689 ;        5.  Initialize loop I for 256 opcodes (00-FF).
                        0032 10690 ;        6.  Store the index I in a location that will be used to load into the
                        0032 10691 ;            WDREG.  The value is used as the opcode.
                        0032 10692 ;        7.  Loop on error from here.
                        0032 10693 ;        8.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
                        0032 10694 ;            is used to get the IRD counter to 1 without sourcing an address
                        0032 10695 ;            from the IRDX roms (ie., by doing an IRDX).
                        0032 10696 ;        9.  Execute the following test microcode (performs the IRD1):
                        0032 10697 ;               a.  NOP to get the RDM up to speed.
                        0032 10698 ;               b.  Read the WDREG into RTEMP2 (opcode).
                        0032 10699 ;               c.  Load the operands into the LONLIT register.
                        0032 10700 ;               d.  Store the operands into the Q register to prepare for ORing
                        0032 10701 ;                   the opcode with the operands.
                        0032 10702 ;               e.  OR the opcode and operands together (XB0 data).
                        0032 10703 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
                        0032 10704 ;               g.  Zero the VA.
                        0032 10705 ;               h.  Validate cache location 0 by first writing the data in
                        0032 10706 ;                   RTEMP2 then reading the data back.
                        0032 10707 ;               i.  Update the VA by 4.
                        0032 10708 ;               j.  Load the second operand data into the LONLIT register
                        0032 10709 ;                   (XB1 data).
                        0032 10710 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
                        0032 10711 ;               l.  Validate cache location 4 by first writing the data in
                        0032 10712 ;                   the LONLIT register then reading the data back.
                        0032 10713 ;               m.  Load the PC with zero to cause a prefetch to take place.
                        0032 10714 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
                        0032 10715 ;                   tion/operand specifier evaluation.
```

0032 10737 ;            16.  Re-enable CTRL/P interrupts then skip to next tests.
0032 10738 ;
0032 10739 ;            Subtest 2
0032 10740 ;
0032 10741 ;            17.  Load the FPA disable bit (bit <5> equal to 0).
0032 10742 ;            18.  Loop on error from here.
0032 10743 ;            19.  Set-up to expect micro trap.
0032 10744 ;            20.  Execute the test microcode.  This is done only to get the FPA to
0032 10745 ;                 a state where it can be disabled or enabled.  If this had not been
0032 10746 ;                 done before then the FPA would be setting in the initialize state
0032 10747 ;                 which forces FPA enable.
0032 10748 ;            21.  Execute the following microcode to disable the FPA:
0032 10749 ;                    a.  NOP to get the RDM up to speed.
0032 10750 ;                    b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 10751 ;                        to the FPA.
0032 10752 ;                    c.  Perform a NO.FPA test to insure that the FPA got disabled.
0032 10753 ;                    d.  Halt.
0032 10754 ;            22.  Check the Trap register to insure that the FPA got disabled.
0032 10755 ;            23.  If the FPA is not disabled, then signal an error.
0032 10756 ;            24.  Set-up flag to expect a micro trap.
0032 10757 ;            25.  Initialize loop I for 256 opcodes (00-FF).
0032 10758 ;            26.  Store the index I in a location that will be used to load into the
0032 10759 ;                 WDREG.  The value is used as the opcode.
0032 10760 ;            27.  Loop on error from here.
0032 10761 ;            28.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 10762 ;                 is used to get the IRD counter to 1 without sourcing an address
0032 10763 ;                 from the IRDX roms (ie., by doing an IRDX).
0032 10764 ;            29.  Execute the following test microcode:
0032 10765 ;                    a.  NOP to get the RDM up to speed.
0032 10766 ;                    b.  Read the WDREG into RTEMP2 (opcode).
0032 10767 ;                    c.  Load the operands into the LONLIT register.
0032 10768 ;                    d.  Store the operands into the Q register to prepare for ORing
0032 10769 ;                        the opcode with the operands.
0032 10770 ;                    e.  OR the opcode and operands together (XB0 data).
```

```
0032 10771 ;                f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 10772 ;                g.  Zero the VA.
0032 10773 ;                h.  Validate cache location 0 by first writing the data in
0032 10774 ;                    RTEMP2 then reading the data back.
0032 10775 ;                i.  Update the VA by 4.
0032 10776 ;                j.  Load the second operand data into the LONLIT register
0032 10777 ;                    (XB1 data).
0032 10778 ;                k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0032 10779 ;                l.  Validate cache location 4 by first writing the data in
0032 10780 ;                    the LONLIT register then reading the data back.
0032 10781 ;                m.  Load the PC with zero to cause a prefetch to take place.
0032 10782 ;                n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 10783 ;                    tion/operand specifier evaluation.
0032 10784 ;                o.  Halt.
0032 10785 ;        30.  Perform the following test microcode.
0032 10786 ;                a.  NOP to get the RDM up to speed.
0032 10787 ;                b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 10788 ;                c.  Halt.
0032 10789 ;        31.  Load DCS location 12 with a BUT/IRDX micro order.
0032 10790 ;        32.  Perform the following test microcode (performs the IRDX with the
0032 10791 ;             IRD counter = 1):
0032 10792 ;                a.  NOP to get the RDM up to speed.
0032 10793 ;                b.  Do an IRDX and strobe the VBUS.
0032 10794 ;                c.  Halt.
0032 10795 ;        33.  Compare the VBUS data with the expected value and bit position
0032 10796 ;             from the VBUS Table.
0032 10797 ;        34.  If the two do not equal, execute the following microcode and
0032 10798 ;             signal an error (this is done to set-up for printing RTEMP0 & 1
0032 10799 ;             on the error callout):
0032 10800 ;                a.  NOP to get the RDM up to speed.
0032 10801 ;                b.  Load RTEMP0 with the contents of M[TEMP8]
0032 10802 ;                c.  Load RTEMP1 with the contents of M[TEMP9]
0032 10803 ;                d.  Halt
0032 10804 ;        35.  Continue with loop I for the 256 VAX opcodes.
0032 10805 ;        36.  Go to Subtest 3.
0032 10806 ;
0032 10807 ;        Subtest 3
0032 10808 ;
0032 10809 ;        37.  Load the FPA enable bit (bit <5> equal to 1).
0032 10810 ;        38.  Loop on error from here.
0032 10811 ;        39.  Set-up to expect micro trap.
0032 10812 ;        40.  Execute the following microcode to enable the FPA:
0032 10813 ;                a.  NOP to get the RDM up to speed.
0032 10814 ;                b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 10815 ;                    to the FPA.
0032 10816 ;                c.  Perform a NO.FPA test to insure that the FPA got enabled.
0032 10817 ;                d.  Halt.
0032 10818 ;        41.  Check the Trap register to insure that the FPA got enabled.
0032 10819 ;        42.  If the FPA is not enabled, then signal an error.
0032 10820 ;        43.  Set-up flag to expect a micro trap.
0032 10821 ;        44.  Initialize loop I for 256 opcodes (00-FF).
0032 10822 ;        45.  Store the index I in a location that will be used to load into the
0032 10823 ;             WDREG.  The value is used as the opcode.
0032 10824 ;        46.  Loop on error from here.
0032 10825 ;        47.  Set then Clear the DCLO bit in the RDCTRL register to perform an
```

```
0032 10826 ;            initialize.  This is done because when the test microcode
0032 10827 ;            executes, if the opcode was an FP opcode then there is a
0032 10828 ;            possibility that the processor could be setting there in an
0032 10829 ;            FPAWAIT state (M clock and D clock stalled).  If this were to
0032 10830 ;            happen then the cpu clocks would no longer run and the remaining
0032 10831 ;            test opcodes would fail.
0032 10832 ;       48.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 10833 ;            is used to get the IRD counter to 1 without sourcing an address
0032 10834 ;            from the IRDX roms (ie., by doing an IRDX).
0032 10835 ;       49.  Execute the following test microcode:
0032 10836 ;               a.  NOP to get the RDM up to speed.
0032 10837 ;               b.  Read the WDREG into RTEMP2 (opcode).
0032 10838 ;               c.  Load the operands into the LONLIT register.
0032 10839 ;               d.  Store the operands into the Q register to prepare for ORing
0032 10840 ;                   the opcode with the operands.
0032 10841 ;               e.  OR the opcode and operands together (XB0 data).
0032 10842 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 10843 ;               g.  Zero the VA.
0032 10844 ;               h.  Validate cache location 0 by first writing the data in
0032 10845 ;                   RTEMP2 then reading the data back.
0032 10846 ;               i.  Update the VA by 4.
0032 10847 ;               j.  Load the second operand data into the LONLIT register
0032 10848 ;                   (XB1 data).
0032 10849 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0032 10850 ;               l.  Validate cache location 4 by first writing the data in
0032 10851 ;                   the LONLIT register then reading the data back.
0032 10852 ;               m.  Load the PC with zero to cause a prefetch to take place.
0032 10853 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 10854 ;                   tion/operand specifier evaluation.
0032 10855 ;               o.  Halt.
0032 10856 ;       50.  Perform the following test microcode.
0032 10857 ;               a.  NOP to get the RDM up to speed.
0032 10858 ;               b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 10859 ;               c.  Halt.
0032 10860 ;       51.  Load DCS location 12 with a BUT/IRDX micro order.
0032 10861 ;       52.  Perform the following test microcode (performs the IRDX with the
0032 10862 ;            IRD counter = 1):
0032 10863 ;               a.  NOP to get the RDM up to speed.
0032 10864 ;               b.  Do an IRDX and strobe the VBUS.
0032 10865 ;               c.  Halt.
0032 10866 ;       53.  Compare the VBUS data with the expected value and bit position
0032 10867 ;            from the VBUS Table.
0032 10868 ;       54.  If the two do not equal, execute the following microcode and
0032 10869 ;            signal an error (this is done to set-up for printing RTEMP0 & 1
0032 10870 ;            on the error callout):
0032 10871 ;               a.  NOP to get the RDM up to speed.
0032 10872 ;               b.  Load RTEMP0 with the contents of M[TEMP8]
0032 10873 ;               c.  Load RTEMP1 with the contents of M[TEMP9]
0032 10874 ;               d.  Halt
0032 10875 ;       55.  Continue with loop I for the 256 VAX opcodes.
0032 10876 ;       56.  Re-enable CTRL/P interrupts.
0032 10877 ;       57.  Skip to next tests.
0032 10878 ;
0032 10879 ; TEST PATTERNS
0032 10880 ;
```

```
0032 10881 ;       For this test the opcodes are generated by a simple count pattern.  The
0032 10882 ;       opcodes are based on the 256 base machine instructions as specified in
0032 10883 ;       the VAX architecture handbook.  The generated opcodes are written to
0032 10884 ;       the CPU and combined (ORed) with three bytes of operand data to form
0032 10885 ;       a machine instruction.  The operands all specify Register Deferred mode
0032 10886 ;       using registers 0-6 and are loaded from the LONLIT register.
0032 10887 ;
0032 10888 ;       Also required are two tables of expected VBUS values for the second
0032 10889 ;       IRDX cycle.  One table contains the VBUS values for the second IRDX
0032 10890 ;       when the FPA is disabled, the other for when it is enabled.
0032 10891 ;
0032 10892 ; LOGIC DESCRIPTION
0032 10893 ;
0032 10894 ;       This test will check the validity of the IRDX roms on the DPM module.
0032 10895 ;       The IRDX roms are addressed by bits <7:0> of the Instruction Register.
0032 10896 ;       Along with being addressed by the IR, there are three other signals
0032 10897 ;       that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
0032 10898 ;       REG MODE H.  This test will examine every 8th(hex) address starting at
0032 10899 ;       address 6 with FPA disabled and starting at address 4 with FPA enabled.
0032 10900 ;
0032 10901 ; ASSUMPTIONS
0032 10902 ;
0032 10903 ;       This test assumes the following logic has already been tested; the
0032 10904 ;       CPU's data path, the cache, the XB, and the IR and OSR.
0032 10905 ;

0032 12459 ;            38.  Loop on error from here.
0032 12460 ;            39.  Set-up to expect micro trap.
0032 12461 ;            40.  Execute the following microcode to enable the FPA:
0032 12462 ;                    a.  NOP to get the RDM up to speed.
0032 12463 ;                    b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 12464 ;                        to the FPA.
0032 12465 ;                    c.  Perform a NO.FPA test to insure that the FPA got enabled.
0032 12466 ;                    d.  Halt.
0032 12467 ;            41.  Check the Trap register to insure that the FPA got enabled.
0032 12468 ;            42.  If the FPA is not enabled, then signal an error.
0032 12469 ;            43.  Set-up flag to expect a micro trap.
0032 12470 ;            44.  Initialize loop I for 256 opcodes (00-FF).
0032 12471 ;            45.  Store the index I in a location that will be used to load into the
0032 12472 ;                 WDREG.  The value is used as the opcode.
0032 12473 ;            46.  Loop on error from here.
0032 12474 ;            47.  Set then Clear the DCLO bit in the RDCTRL register to perform an
0032 12475 ;                 initialize.  This is done because when the test microcode
```

```
0032 12476 ;            executes, if the opcode was an FP opcode then there is a
0032 12477 ;            possibility that the processor could be setting there in an
0032 12478 ;            FPAWAIT state (M clock and D clock stalled).  If this were to
0032 12479 ;            happen then the cpu clocks would no longer run and the remaining
0032 12480 ;            test opcodes would fail.
0032 12481 ;       48.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 12482 ;            is used to get the IRD counter to 1 without sourcing an address
0032 12483 ;            from the IRDX roms (ie., by doing an IRDX).
0032 12484 ;       49.  Execute the following test microcode:
0032 12485 ;               a.  NOP to get the RDM up to speed.
0032 12486 ;               b.  Read the WDREG into RTEMP2 (opcode).
0032 12487 ;               c.  Load the operands into the LONLIT register.
0032 12488 ;               d.  Store the operands into the Q register to prepare for ORing
0032 12489 ;                   the opcode with the operands.
0032 12490 ;               e.  OR the opcode and operands together (XB0 data).
0032 12491 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 12492 ;               g.  Zero the VA.
0032 12493 ;               h.  Validate cache location 0 by first writing the data in
0032 12494 ;                   RTEMP2 then reading the data back.
0032 12495 ;               i.  Update the VA by 4.
0032 12496 ;               j.  Load the second operand data into the LONLIT register
0032 12497 ;                   (XB1 data).
0032 12498 ;               k.  Store XB1 data in M[TEMP8] in case needed for error callout.
0032 12499 ;               l.  Validate cache location 4 by first writing the data in
0032 12500 ;                   the LONLIT register then reading the data back.
0032 12501 ;               m.  Load the PC with zero to cause a prefetch to take place.
0032 12502 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 12503 ;                   tion/operand specifier evaluation.
0032 12504 ;               o.  Halt.
0032 12505 ;       50.  Perform the following test microcode.
0032 12506 ;               a.  NOP to get the RDM up to speed.
0032 12507 ;               b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 12508 ;               c.  Halt.
0032 12509 ;       51.  Load DCS location 12 with a BUT/IRDX micro order.
0032 12510 ;       52.  Perform the following test microcode (performs the IRDX with the
0032 12511 ;            IRD counter = 1):
0032 12512 ;               a.  NOP to get the RDM up to speed.
0032 12513 ;               b.  Do an IRDX.
0032 12514 ;               c.  Halt.
0032 12515 ;       53.  Compare the contents of the CSTRP register (output from the IRDX
0032 12516 ;            Roms) against the Rom Table.
0032 12517 ;       54.  If the two do not equal, execute the following microcode and
0032 12518 ;            signal an error (this is done to set-up for printing RTEMP0 & 1
0032 12519 ;            on the error callout):
0032 12520 ;               a.  NOP to get the RDM up to speed.
0032 12521 ;               b.  Load RTEMP0 with the contents of M[TEMP8]
0032 12522 ;               c.  Load RTEMP1 with the contents of M[TEMP9]
0032 12523 ;               d.  Halt
0032 12524 ;       55.  Continue with loop I for the 256 VAX opcodes.
0032 12525 ;       56.  Re-enable CTRL/P interrupts.
0032 12526 ;       57.  Skip to next tests.
0032 12527 ;
0032 12528 ; TEST PATTERNS
0032 12529 ;
0032 12530 ;            For this test the opcodes are generated by a simple count pattern.  The
```

```
0032 12531 ;       opcodes are based on the 256 base machine instructions as specified in
0032 12532 ;       the VAX architecture handbook.  The generated opcodes are written to
0032 12533 ;       the CPU and combined (ORed) with three bytes of operand data to form
0032 12534 ;       a machine instruction.  The operands all specify Register Deferred mode
0032 12535 ;       using registers 0-6 and are loaded from the LONLIT register.
0032 12536 ;
0032 12537 ;       Also required are two tables of expected control store addresses for
0032 12538 ;       the second IRDX cycle.  One table contains the expected addresses for
0032 12539 ;       the second IRDX when the FPA is disabled, the other for when it is
0032 12540 ;       enabled.
0032 12541 ;
0032 12542 ; LOGIC DESCRIPTION
0032 12543 ;
0032 12544 ;       This test will check the validity of the IRDX roms on the DPM module.
0032 12545 ;       The IRDX roms are addressed by bits <7:0> of the Instruction Register.
0032 12546 ;       Along with being addressed by the IR, there are three other signals
0032 12547 ;       that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
0032 12548 ;       REG MODE H.  This test will examine every 8th(hex) address starting at
0032 12549 ;       address 6 with FPA disabled and starting at address 4 with FPA enabled.
0032 12550 ;
0032 12551 ; ASSUMPTIONS
0032 12552 ;
0032 12553 ;       This test assumes the following logic has already been tested; the
0032 12554 ;       CPU's data path, the cache, the XB, and the IR and OSR.
0032 12555 ;

                        0032 13018 ;       This test consists of three subtests.  The first subtest will examine
                        0032 13019 ;       the IRDX roms when the Floating Point Accelerator (FPA) is not present
                        0032 13020 ;       in the system.  The second subtest will examine the IRDX roms when the
                        0032 13021 ;       FPA is present but disabled.  The third subtest will examine the IRDX
                        0032 13022 ;       roms when the FPA is present and enabled.  The algorithm is as follows:
                        0032 13023 ;
                        0032 13024 ;        1.  Initialize the processor.
                        0032 13025 ;        2.  Disable CTRL/P interrupts.
                        0032 13026 ;        3.  Check to see if FPA present
                        0032 13027 ;               If FPA present
                        0032 13028 ;                   Then skip to Subtest 2
                        0032 13029 ;               Else fall through to subtest 1
                        0032 13030 ;
                        0032 13031 ;       Subtest 1
                        0032 13032 ;
                        0032 13033 ;        4.  Set-up flag to expect a micro trap.
                        0032 13034 ;        5.  Initialize loop I for 256 opcodes (00-FF).
                        0032 13035 ;        6.  Store the index I in a location that will be used to load into the
                        0032 13036 ;            WDREG.  The value is used as the opcode.
                        0032 13037 ;        7.  Loop on error from here.
                        0032 13038 ;        8.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
                        0032 13039 ;            is used to get the IRD counter to 1 without sourcing an address
                        0032 13040 ;            from the IRDX roms (ie., by doing an IRDX).
                        0032 13041 ;        9.  Execute the following test microcode (performs the IRD1):
                        0032 13042 ;               a.  NOP to get the RDM up to speed.
                        0032 13043 ;               b.  Read the WDREG into RTEMP2 (opcode).
                        0032 13044 ;               c.  Load the operands into the LONLIT register.
                        0032 13045 ;               d.  Store the operands into the Q register to prepare for ORing
                        0032 13046 ;                   the opcode with the operands.
                        0032 13047 ;               e.  OR the opcode and operands together (XB0 data).
                        0032 13048 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
                        0032 13049 ;               g.  Zero the VA.
                        0032 13050 ;               h.  Validate cache location 0 by first writing the data in
                        0032 13051 ;                   RTEMP2 then reading the data back.
                        0032 13052 ;               i.  Update the VA by 4.
                        0032 13053 ;               j.  Load the second operand data into the LONLIT register
                        0032 13054 ;                   (XB1 data).
                        0032 13055 ;               k.  Store XB1 data in M[TEMP9] in case needed for error callout.
                        0032 13056 ;               l.  Validate cache location 4 by first writing the data in
                        0032 13057 ;                   the LONLIT register then reading the data back.
                        0032 13058 ;               m.  Load the PC with zero to cause a prefetch to take place.
                        0032 13059 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
                        0032 13060 ;                   tion/operand specifier evaluation.
```

```
0032 13061 ;                    o.  Halt.
0032 13062 ;            10.  Perform the following test microcode (performs the LOD.INC.BRA?)
0032 13063 ;                    a.  NOP to get the RDM up to speed.
0032 13064 ;                    b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 13065 ;                    c.  Halt.
0032 13066 ;            11.  Load DCS location 12 with a BUT/IRDX micro order.
0032 13067 ;            12.  Perform the following test microcode (performs the IRDX with the
0032 13068 ;                 IRD counter = 1):
0032 13069 ;                    a.  NOP to get the RDM up to speed.
0032 13070 ;                    b.  Do an IRDX and strobe the VBUS.
0032 13071 ;                    c.  Halt.
0032 13072 ;            13.  Compare the VBUS data with the expected value and bit position
0032 13073 ;                 from the VBUS Table.
0032 13074 ;            14.  If the two do not equal, execute the following microcode and
0032 13075 ;                 signal an error (this is done to set-up for printing RTEMP0 & 1
0032 13076 ;                 on the error callout):
0032 13077 ;                    a.  NOP to get the RDM up to speed.
0032 13078 ;                    b.  Load RTEMP0 with the contents of M[TEMP8]
0032 13079 ;                    c.  Load RTEMP1 with the contents of M[TEMP9]
0032 13080 ;                    d.  Halt
0032 13081 ;            15.  Continue with loop I for the 256 VAX opcodes.
0032 13082 ;            16.  Re-enable CTRL/P interrupts then skip to next tests.
0032 13083 ;
0032 13084 ;            Subtest 2
0032 13085 ;
0032 13086 ;            17.  Load the FPA disable bit (bit <5> equal to 0).
0032 13087 ;            18.  Loop on error from here.
0032 13088 ;            19.  Set-up to expect micro trap.
0032 13089 ;            20.  Execute the test microcode.  This is done only to get the FPA to
0032 13090 ;                 a state where it can be disabled or enabled.  If this had not been
0032 13091 ;                 done before then the FPA would be setting in the initialize state
0032 13092 ;                 which forces FPA enable.
0032 13093 ;            21.  Execute the following microcode to disable the FPA:
0032 13094 ;                    a.  NOP to get the RDM up to speed.
0032 13095 ;                    b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 13096 ;                        to the FPA.
0032 13097 ;                    c.  Perform a NO.FPA test to insure that the FPA got disabled.
0032 13098 ;                    d.  Halt.
0032 13099 ;            22.  Check the Trap register to insure that the FPA got disabled.
0032 13100 ;            23.  If the FPA is not disabled, then signal an error.
0032 13101 ;            24.  Set-up flag to expect a micro trap.
0032 13102 ;            25.  Initialize loop I for 256 opcodes (00-FF).
0032 13103 ;            26.  Store the index I in a location that will be used to load into the
0032 13104 ;                 WDREG.  The value is used as the opcode.
0032 13105 ;            27.  Loop on error from here.
0032 13106 ;            28.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 13107 ;                 is used to get the IRD counter to 1 without sourcing an address
0032 13108 ;                 from the IRDX roms (ie., by doing an IRDX).
0032 13109 ;            29.  Execute the following test microcode:
0032 13110 ;                    a.  NOP to get the RDM up to speed.
0032 13111 ;                    b.  Read the WDREG into RTEMP2 (opcode).
0032 13112 ;                    c.  Load the operands into the LONLIT register.
0032 13113 ;                    d.  Store the operands into the Q register to prepare for ORing
0032 13114 ;                        the opcode with the operands.
0032 13115 ;                    e.  OR the opcode and operands together (XB0 data).
```

```
0032 13116 ;                f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 13117 ;                g.  Zero the VA.
0032 13118 ;                h.  Validate cache location 0 by first writing the data in
0032 13119 ;                    RTEMP2 then reading the data back.
0032 13120 ;                i.  Update the VA by 4.
0032 13121 ;                j.  Load the second operand data into the LONLIT register
0032 13122 ;                    (XB1 data).
0032 13123 ;                k.  Store XB1 data in M[TEMP9] in case needed for error callout.
0032 13124 ;                l.  Validate cache location 4 by first writing the data in
0032 13125 ;                    the LONLIT register then reading the data back.
0032 13126 ;                m.  Load the PC with zero to cause a prefetch to take place.
0032 13127 ;                n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 13128 ;                    tion/operand specifier evaluation.
0032 13129 ;                o.  Halt.
0032 13130 ;        30.  Perform the following test microcode.
0032 13131 ;                a.  NOP to get the RDM up to speed.
0032 13132 ;                b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 13133 ;                c.  Halt.
0032 13134 ;        31.  Load DCS location 12 with a BUT/IRDX micro order.
0032 13135 ;        32.  Perform the following test microcode (performs the IRDX with the
0032 13136 ;             IRD counter = 1):
0032 13137 ;                a.  NOP to get the RDM up to speed.
0032 13138 ;                b.  Do an IRDX and strobe the VBUS.
0032 13139 ;                c.  Halt.
0032 13140 ;        33.  Compare the VBUS data with the expected value and bit position
0032 13141 ;             from the VBUS Table.
0032 13142 ;        34.  If the two do not equal, execute the following microcode and
0032 13143 ;             signal an error (this is done to set-up for printing RTEMP0 & 1
0032 13144 ;             on the error callout):
0032 13145 ;                a.  NOP to get the RDM up to speed.
0032 13146 ;                b.  Load RTEMP0 with the contents of M[TEMP8]
0032 13147 ;                c.  Load RTEMP1 with the contents of M[TEMP9]
0032 13148 ;                d.  Halt
0032 13149 ;        35.  Continue with loop I for the 256 VAX opcodes.
0032 13150 ;        36.  Go to Subtest 3.
0032 13151 ;
0032 13152 ;        Subtest 3
0032 13153 ;
0032 13154 ;        37.  Load the FPA enable bit (bit <5> equal to 1).
0032 13155 ;        38.  Loop on error from here.
0032 13156 ;        39.  Set-up to expect micro trap.
0032 13157 ;        40.  Execute the following microcode to enable the FPA:
0032 13158 ;                a.  NOP to get the RDM up to speed.
0032 13159 ;                b.  Read the RDM WDREG onto the W Bus and then write the W Bus
0032 13160 ;                    to the FPA.
0032 13161 ;                c.  Perform a NO.FPA test to insure that the FPA got enabled.
0032 13162 ;                d.  Halt.
0032 13163 ;        41.  Check the Trap register to insure that the FPA got enabled.
0032 13164 ;        42.  If the FPA is not enabled, then signal an error.
0032 13165 ;        43.  Set-up flag to expect a micro trap.
0032 13166 ;        44.  Initialize loop I for 256 opcodes (00-FF).
0032 13167 ;        45.  Store the index I in a location that will be used to load into the
0032 13168 ;             WDREG.  The value is used as the opcode.
0032 13169 ;        46.  Loop on error from here.
0032 13170 ;        47.  Set then Clear the DCLO bit in the RDCTRL register to perform an
```

```
0032 13171 ;            initialize.  This is done because when the test microcode
0032 13172 ;            executes, if the opcode was an FP opcode then there is a
0032 13173 ;            possibility that the processor could be setting there in an
0032 13174 ;            FPAWAIT state (M clock and D clock stalled).  If this were to
0032 13175 ;            happen then the cpu clocks would no longer run and the remaining
0032 13176 ;            test opcodes would fail.
0032 13177 ;       48.  Set-up DCS location 12 with a BUT/LOD.INC.BRA?,NEXT/1800.  This
0032 13178 ;            is used to get the IRD counter to 1 without sourcing an address
0032 13179 ;            from the IRDX roms (ie., by doing an IRDX).
0032 13180 ;       49.  Execute the following test microcode:
0032 13181 ;               a.  NOP to get the RDM up to speed.
0032 13182 ;               b.  Read the WDREG into RTEMP2 (opcode).
0032 13183 ;               c.  Load the operands into the LONLIT register.
0032 13184 ;               d.  Store the operands into the Q register to prepare for ORing
0032 13185 ;                   the opcode with the operands.
0032 13186 ;               e.  OR the opcode and operands together (XB0 data).
0032 13187 ;               f.  Store XB0 data in M[TEMP8] in case needed for error callout.
0032 13188 ;               g.  Zero the VA.
0032 13189 ;               h.  Validate cache location 0 by first writing the data in
0032 13190 ;                   RTEMP2 then reading the data back.
0032 13191 ;               i.  Update the VA by 4.
0032 13192 ;               j.  Load the second operand data into the LONLIT register
0032 13193 ;                   (XB1 data).
0032 13194 ;               k.  Store XB1 data in M[TEMP8] in case needed for error callout.
0032 13195 ;               l.  Validate cache location 4 by first writing the data in
0032 13196 ;                   the LONLIT register then reading the data back.
0032 13197 ;               m.  Load the PC with zero to cause a prefetch to take place.
0032 13198 ;               n.  Do an IRD1 to init the IRD counter and prepare for instruc-
0032 13199 ;                   tion/operand specifier evaluation.
0032 13200 ;               o.  Halt.
0032 13201 ;       50.  Perform the following test microcode.
0032 13202 ;               a.  NOP to get the RDM up to speed.
0032 13203 ;               b.  Do an BUT/LOD.INC.BRA?,NEXT/1800
0032 13204 ;               c.  Halt.
0032 13205 ;       51.  Load DCS location 12 with a BUT/IRDX micro order.
0032 13206 ;       52.  Perform the following test microcode (performs the IRDX with the
0032 13207 ;            IRD counter = 1):
0032 13208 ;               a.  NOP to get the RDM up to speed.
0032 13209 ;               b.  Do an IRDX and strobe the VBUS.
0032 13210 ;               c.  Halt.
0032 13211 ;       53.  Compare the VBUS data with the expected value and bit position
0032 13212 ;            from the VBUS Table.
0032 13213 ;       54.  If the two do not equal, execute the following microcode and
0032 13214 ;            signal an error (this is done to set-up for printing RTEMP0 & 1
0032 13215 ;            on the error callout):
0032 13216 ;               a.  NOP to get the RDM up to speed.
0032 13217 ;               b.  Load RTEMP0 with the contents of M[TEMP8]
0032 13218 ;               c.  Load RTEMP1 with the contents of M[TEMP9]
0032 13219 ;               d.  Halt
0032 13220 ;       55.  Continue with loop I for the 256 VAX opcodes.
0032 13221 ;       56.  Re-enable CTRL/P interrupts.
0032 13222 ;       57.  Skip to next tests.
0032 13223 ;
0032 13224 ; TEST PATTERNS
0032 13225 ;
```

```
                        0032 13226 ;       For this test the opcodes are generated by a simple count pattern.  The
                        0032 13227 ;       opcodes are based on the 256 base machine instructions as specified in
                        0032 13228 ;       the VAX architecture handbook.  The generated opcodes are written to
                        0032 13229 ;       the CPU and combined (ORed) with three bytes of operand data to form
                        0032 13230 ;       a machine instruction.  The operands all specify Register Deferred mode
                        0032 13231 ;       using registers 0-6 and are loaded from the LONLIT register.
                        0032 13232 ;
                        0032 13233 ;       Also required are two tables of expected VBUS values for the second
                        0032 13234 ;       IRDX cycle.  One table contains the VBUS values for the second IRDX
                        0032 13235 ;       when the FPA is disabled, the other for when it is enabled.
                        0032 13236 ;
                        0032 13237 ; LOGIC DESCRIPTION
                        0032 13238 ;
                        0032 13239 ;       This test will check the validity of the IRDX roms on the DPM module.
                        0032 13240 ;       The IRDX roms are addressed by bits <7:0> of the Instruction Register.
                        0032 13241 ;       Along with being addressed by the IR, there are three other signals
                        0032 13242 ;       that affect the address.  They are IRD CTR 0 H, FPA ENABLED L, and
                        0032 13243 ;       REG MODE H.  This test will examine every 8th(hex) address starting at
                        0032 13244 ;       address 6 with FPA disabled and starting at address 4 with FPA enabled.
                        0032 13245 ;

Performance indicators

Phase	Page faults	CPU Time	Elapsed Time
Initialization	41	00:00:00.10	00:00:07.82
Command processing	880	00:00:00.69	00:00:06.23
Pass 1	3653	00:01:38.31	00:03:37.90
Symbol table sort	0	00:00:00.49	00:00:00.60

Pass 2	45	00:00:30.50	00:01:20.26
Symbol table output	2	00:00:00.14	00:00:00.14
Psect synopsis output	2	00:00:00.34	00:00:00.95
Cross-reference output	0	00:00:00.00	00:00:00.00
Assembler run totals	4623	00:02:10.57	00:05:13.90

The working set limit was 6450 pages.
1473054 bytes (2878 pages) of virtual memory were used to buffer the intermediate code.
There were 30 pages of symbol table space allocated to hold 352 non-local and 229 local symbols.
15400 source lines were read in Pass 1, producing 357 object records in Pass 2.
96 pages of virtual memory were used to define 44 macros.

+----------------------------+
! Macro library statistics !
+----------------------------+

Macro library name	Macros defined
DISK$UCODPACK00:[VAX750]COMETMAC.MLB;805	44
SYS$COMMON:[SYSLIB]STARLET.MLB;2	0
TOTALS (all libraries)	44

1810 GETS were required to define 44 macros.

There were 0 errors, 12 warnings and 0 information messages, on lines:

0000     27 ;
0000     28 ; REVISION HISTORY
0000     29 ;
0000     30 ; 00-01 Tom Groetzinger 4-FEB-1980
0000     31 ;       Started file.
0000     32 ;
0000     33 ; 00-02 Dave Spain      27-FEB-1980
0000     34 ;       Added CS BUS INTEGRITY test.
0000     35 ;
0000     36 ; 00-03 Tom Groetzinger 12-MAR-1980
0000     37 ;       Added five tests.
0000     38 ;
0000     39 ; 00-04 Tom Groetzinger 17-MAR-1980
0000     40 ;       Added SRK,SRM callouts to some tests.
0000     41 ;
0000     42 ; 00-05 Tom Groetzinger 17-MAR-1980
0000     43 ;       Improved tests 7 and 16 to increase coverage due to Westboro feedback
0000     44 ;
0000     45 ; 00-06 Tom Groetzinger 17-MAR-1980
0000     46 ;       Debugged test 16 dueu to major rewrite
0000     47 ;
0000     48 ; 00-07 Tom Groetzinger 17-MAR-1980
0000     49 ;       Added 9 Super Rotator tests
0000     50 ;
0000     51 ; 01-08 Dave Spain       4-APR-80
0000     52 ;       Added 4 Micro-sequencer tests for offical release.
0000     53 ;
0000     54 ; 01-09 Bill Landry     4-APR-1980
0000     55 ;       Added the XB, PREFETCH and IRD tests from ECKAC.SRC so
0000     56 ;       manufacturing can run one tape for DPM.
0000     57 ;
0000     58 ; 00-10 Bill Landry     4-APR-1980
0000     59 ;       Let's save version 1.0 for our first SDC release.
0000     60 ;
0000     61 ; 00-11 Tom Groetzinger 7-APR-1980
0000     62 ;       Added 2 ALK Tests
0000     63 ;
0000     64 ; 00-12 Tom Groetzinger 8-APR-1980
0000     65 ;       Deleted last 2 D Register outputs from ALK Test #6
0000     66 ;
0000     67 ; 00-13 Tom Groetzinger 14-APR-1980
0000     68 ;       Added D Register output to ALK test #6
0000     69 ;
0000     70 ; 00-14 Dave Spain      25-APR-1980
0000     71 ;       Changed mask on the micro-sequencer tests to ignore bit 13 of the
0000     72 ;       Control Store address.
0000     73 ;
0000     74 ; 00-15 Dave Spain      28-APR-1980
0000     75 ;       Fixed bug in ALK Tests 6 and 7 by replacing VSIZE/1 micro order with a
0000     76 ;       SIZE[LONG] macro in micro words 6 and 3 respectively.
0000     77 ;
0000     78 ; 00-16 Dave Spain      29-APR-1980
0000     79 ;       Changed mask on CS address for Instruction Address Decode test from
0000     80 ;       3FFF to 1FFF to ignore bit 13 of Control Store address.
```

```
0000     81 ;
0000     82 ; 00-17 Dave Spain      30-APR-1980
0000     83 ;       Added CCS module to error callout for Control Store Bus Integrity test.
0000     84 ;
0000     85 ; 00-18 Dave Spain       9-MAY-1980
0000     86 ;       Added SRM gate array to error callout routine in RTMP0 and RTEMP
0000     87 ;       Sratchpad tests.
0000     88 ;
0000     89 ; 00-19 Bill Landry     10-JUN-1980
0000     90 ;       Added RDM tests to beginning of tape
0000     91 ;
0000     92 ; 01-00 Bill Landry/Dave Spain  13-JUN-1980
0000     93 ;       Added macro file to title section and compatibility mode IRD tests
0000     94 ;       then submitted to RELEASE ENGINERRING.
0000     95 ;
0000     96 ; 01-01 Dave Spain      19-JUN-1980
0000     97 ;       Fixed prefetch incrementer test to clear out cache data after every
0000     98 ;       prefetch. This will prevent the test from mistaking bad addresses from
0000     99 ;       good ones.
0000    100 ;
0000    101 ; 01-02 Dave Spain       2-JUL-1980
0000    102 ;       Added CM Second IRDX tests to file.
0000    103 ;
0000    104 ; 01-03 Dave Spain      18-AUG-1980
0000    105 ;       Added CM branch test to file.
0000    106 ;
0000    107 ; 01-04 Dave Spain      10-SEPT-1980
0000    108 ;       Fixed "DEFAULT MTEMP0 TEST"
0000    109 ;
0000    110 ; 01-05 Bill Landry     11-SEPT-1980
0000    111 ;       Revised RDM to CMI tests
0000    112 ;
0000    113 ; 02-00 Dave Spain      28-SEPT-1980
0000    114 ;       Added rotator tests to file and submitted to SDC.
0000    115 ;
0000    116 ; 02-01 Dave Spain      28-OCT-1980
0000    117 ;       Added QV flag to tests to be run by manufacturing.
0000    118 ;
0000    119 ; 02-02 Bill Landry     10-NOV-1980
0000    120 ;       Added tests for TOK and SAC gate arrays.
0000    121 ;
0000    122 ; 02-03 Bill Landry     13-NOV-1980
0000    123 ;       Added test of REI CHECK
0000    124 ;
0000    125 ; 03-00 Dave Spain      17-NOV-1980
0000    126 ;       Added rotator tests 23-28 and released to SDC.
0000    127 ;
0000    128 ; 03-01 Dave Spain      10-DEC-1980
0000    129 ;       Added rotator tests 29-42.
0000    130 ;
0000    131 ; 03-02 Bill Landry     11-DEC-1980
0000    132 ;       Fixed bug in CS ADDRESS test
0000    133 ;
0000    134 ; 03-03 Dave Spain      12-DEC-1980
0000    135 ;       Enhanced Rotator Test 1 to call out ALP slices.
0000    136 ;
0000    137 ; 03-04 Bill Landry     16-DEC-1980
```

```
0000    138 ;       Added DSIZE ROM tests
0000    139 ;
0000    140 ; 03-05 Bill Landry     31-DEC-1980
0000    141 ;       Last great act of 80. Separated DPM and RDM tests into two files.
0000    142 ;
0000    143 ; 04-00 Bill Landry     5-JAN-1981
0000    144 ;       Submitted to RELEASE ENGINERRING
0000    145 ;
0000    146 ; 04-01 Bill Landry     14-JAN-1981
0000    147 ;       Revised INTERVAL TIMER INTERRUPT TEST to fix bug caused by INT PEND
0000    148 ;       ECO
0000    149 ;
0000    150 ; 04-02 Dave Spain      16-JAN-1981
0000    151 ;       Fixed error callout in CS Parity Error, XB, and Prefetch Incrementer
0000    152 ;       tests and added seven new rotator tests.
0000    153 ;
0000    154 ; 04-03 Bill Landry     4-FEB-1981
0000    155 ;       Added tests for CCC gate array
0000    156 ;
0000    157 ; 04-04 Dave Spain      9-FEB-1981
0000    158 ;       Changed the names of rotator tests 23-33.
0000    159 ;
0000    160 ; 04-05 Bill Landry     24-FEB-1981
0000    161 ;       Added tests for DPM discrete branching logic.
0000    162 ;
0000    163 ; 04-06 Bill Landry     27-FEB-1981
0000    164 ;       Added tests for branching logic in PHB gate array.
0000    165 ;
0000    166 ; 05-00 Dave Spain       1-MAR-1981
0000    167 ;       Added 5 SRK status rotator tests and submitted to SDC.
0000    168 ;
0000    169 ; 05-01 Dave Spain      25-MAR-1981
0000    170 ;       Fixed a loop on test bug in the Alu Functions Test by adding a LDFIELD
0000    171 ;       pseudo-op that reinitializes the ROT field in Subtest 1.
0000    172 ;
0000    173 ; 05-02 Bill Landry     25-MAR-1981
0000    174 ;       Fixed bug in BUT/NO.FPA test.  I was branching on the wrong conditions.
0000    175 ;
0000    176 ; 05-03 Dave Spain      14-APR-1981
0000    177 ;       Cleaned up documentation for R Scratchpads Write All Cells Test.
0000    178 ;
0000    179 ; 06-00 Bill Landry     2-MAY-1981
0000    180 ;       Added SPA branching, CON registers, TU58 registers, and CCS PARITY
0000    181 ;       tests.  Submitted to Release Engineering.
0000    182 ;
0000    183 ; 06-01 Dave Spain      17-JUN-1981
0000    184 ;       Replaced the old IRD1 Instruction Address Decode test with two new
0000    185 ;       tests that toggle the PSL's FPD bit and can handle an FPA.
0000    186 ;
0000    187 ; 06-02 Bill Landry     19-AUG-1981
0000    188 ;       Fixed bugs created by introduction of FPA option.
0000    189 ;       Replaced all references to COMET with the word CPU.
0000    190 ;       Fixed typing error in vbus data of CPU CLOCK TEST.
0000    191 ;       Submitted to RELEASE ENGINEERING.
0000    192 ;
0000    193 ; 06-03 Bill Landry     24-SEPT-1981
0000    194 ;       Fixed potential clock problem with FPA in Z BIT TEST 1.
```

```
0000    195 ;
0000    196 ; 06-04 Bill Landry     9-OCT-1981
0000    197 ;       Added changes for ECO L0002-TW002
0000    198 ;
0000    199 ; 07-00 Bill Landry     31-OCT-1981
0000    200 ;       Removed changes for ECO L0002-TW002.  ECO is on hold.
0000    201 ;       Added tests for FPA to CPU interface logic
0000    202 ;       Moved WCS test to MIC tape
0000    203 ;       Submitted to RELEASE ENGINEERING.
0000    204 ;
0000    205 ; 07-01 Bill Landry     13-NOV-1981
0000    206 ;       Stopped release of 7.0
0000    207 ;       Added FPA TRAP LOGIC TEST
0000    208 ;       Enhanced error messages for FPA
0000    209 ;       Resubmitted to RELEASE ENGINEERING
0000    210 ;
0000    211 ; 07-02 Bill Landry     20-NOV-1981
0000    212 ;       Stopped release of 7.1
0000    213 ;       Enhanced FPA ENABLE/DISABLE TEST to check for MSEQ INIT
0000    214 ;       Resubmitted to RELEASE ENGINEERING
0000    215 ;
0000    216 ; 07-03 Dave Shull      26-Mar-1982
0000    217 ;       Added the ERRLOOP pseudo to the Rotator Extract tests which were
0000    218 ;       missing these and couldn't be looped on.
0000    219 ;
0000    220 ; 07-04 Dave Shull      05-Apr-1982
0000    221 ;       Removed all BEGINSA and ENDSA pseudo's.
0000    222 ;       Submitted to RELEASE ENGINEERING
0000    223 ;
0000    224 ; 07-05 Dave Shull      21-May-1982
0000    225 ;       Add a subtest to the Micro Sequencer Stack Test that will test bits
0000    226 ;       11 and 12 of the micro stack.
0000    227 ;
0000    228 ; 07-06 Dave Shull      24-May-1982
0000    229 ;       Changed documentation in the CM Odd Address BUT Test to reflect the
0000    230 ;       ECO L0002-TW002
0000    231 ;
0000    232 ; 08-00 Dave Shull      18-Jun-1982
0000    233 ;       Added 10 new tests.  Two of those tests are an addition to the existing
0000    234 ;       IRD1 rom tests.  These 2 new tests check the signal ROM OS INH H.
0000    235 ;       The other 8 new tests check the validity of the IRDX ROMs.  They check
0000    236 ;       both the address and the signal ROM OS INH H.
0000    237 ;
0000    238 ; 08-01 Dave Shull      22-Jun-1982
0000    239 ;       Added a subtest to the Register Backup Stack test that will check the
0000    240 ;       bit that records Increment/Decrement of the GPR.
0000    241 ;
0000    242 ; 09-00 Dave Shull      03-Nov-1982
0000    243 ;       Added two new Tests for coverage the new PCS (L0008) module.
0000    244 ;
0000    245 ; 09-01 Dave Smith      15-May-1983
0000    246 ;       Correct DCS in ALK test 3,6,7. Disabled ALP's on the WBUS.
0000    247 ;
0000    248 ; 09-02 Joe Zagarella   20-Jan-1987
0000    249 ;       Fixed bug introduced by L0003-YA module in tests CE-D3, and D6-DB
0000    250 ;--

0000     5 ; Revision History
0000     6 ;
0000     7 ; 28    Dave Spain      22-Jun-82
0000     8 ;       Removed LOAD FPA SIGN REG and LOAD FPA SIGN REGS macros.
0000     9 ;       Decided not to use them.
0000    10 ;
0000    11 ; 27    Dave Spain      15-Jun-82
0000    12 ;       Added LOAD FPA SIGN REG and LOAD FPA SIGN REGS macros.
0000    13 ;
0000    14 ; 26    Dave Spain      19-May-82
0000    15 ;       Added M[]_FPA macro.
0000    16 ;
0000    17 ; 25    Rich Lewis      23-Feb-82
0000    18 ;       Added PSL_WB, M[]_R[].OR.NIB0(M), WB_FPA CCR, WB_FPA TCR, Q_R[].ASL.P,
0000    19 ;       RDM_M[].XZ.OR.R[], FPA_WB macros
0000    20 ;
0000    21 ; 24    Dave Spain      02-Feb-82
0000    22 ;       Added FPA_R[]+M[] macro.
0000    23 ;
0000    24 ; 23    Bill Landry     22-OCT-81
0000    25 ;       Added PSL_RDM macro
0000    26 ;
0000    27 ; 22    Dave Spain       5 Oct 81
0000    28 ;       Added RDM_FPA and FPA_M[] FPA_RDM macros.
0000    29 ;
0000    30 ; 21    Bill Landry     29 Sept 81
0000    31 ;       Added FPA macro, FPA_M[] FPA_R[].
0000    32 ;
0000    33 ; 20    Dave Spain      14 Aug 81
0000    34 ;       Added the TESTFPA [] macro.
0000    35 ;
0000    36 ; 19    Dave Spain      18 July 81
0000    37 ;       Added the following FPA macros, FPA_RDM and FPA_R[].
0000    38 ;
0000    39 ; 18    Dave Spain      24 Sept 80
0000    40 ;       Added RDM_Q macro. This macro uses the ALU.
0000    41 ;
0000    42 ; 17    Bill Landry     23 Sept 80
0000    43 ;       Added macro VA_VA-ZLIT0[] for testing memory in decending order.
0000    44 ;
0000    45 ; 16    Dave Spain      27 August 80
0000    46 ;       Changed RDM_Q macro to RDM_Q Q_D. This more accurately reflects macro.
0000    47 ;
0000    48 ; 15    Bill Landry     4 June 80
0000    49 ;       Deleted BUS/PRB.RD.PTE from macro CLRTB.VA_VA and CLRCH.VA_VA to
0000    50 ;       satisfy validity checks.
0000    51 ;
0000    52 ; 14    Dave Spain      23 May 80
0000    53 ;       Added BUS/PRB.RD.PTE to the clear cache and clear TB macros for Mr.
0000    54 ;       Bill.
0000    55 ;
0000    56 ; 13    Dave Spain      14 Apr 80
0000    57 ;       Added SIZE[] or VSIZE/1 to some macros. This allows version 65 of
0000    58 ;       the COMET micro-code defines to run.
0000    59 ;
```

```
0000     60 ; 12    Bill Landry      1 Apr 80
0000     61 ;       Added BUS/PRB.RD micro order to RDM_TB macro to compensate for timing
0000     62 ;       problem in ADD gate array.  This is not an APRIL FOOL!
0000     63 ;
0000     64 ; 11    Dave Spain      27 Mar 80
0000     65 ;       Fixed TB macro's to include MSRC/VA to prevent validity failure.
0000     66 ;
0000     67 ; 10    Bill Landry     19 Mar 80
0000     68 ;       Added Q_R[].RL.P and VA_Q.OR.R[]
0000     69 ;
0000     70 ; 09    Bill Landry     19 Mar 80
0000     71 ;       Deleted TB_R[].RL.P.OR.D
0000     72 ;
0000     73 ; 08    Bill Landry     18 Mar 80
0000     74 ;       Added VA_R[].RL.P
0000     75 ;
0000     76 ; 07    Bill Landry     07 Mar 80
0000     77 ;       Added Q_M[].RL.PTE
0000     78 ;
0000     79 ; 06    Dave Spain      06 Mar 80
0000     80 ;       Changed TB_R[].RL.P macro to TB_R[].RL.P.OR.D.
0000     81 ;
0000     82 ; 05    Dave Spain      03 Mar 80
0000     83 ;       Added TB_R[].RL.P macro for Bill Landry.
0000     84 ;
0000     85 ; 04    Dave Spain      22 Feb 80
0000     86 ;       Added CLRTB.VA_R[] macro for Bill Landry.
0000     87 ;
0000     88 ; 03    Dave Spain      30 Jan 80
0000     89 ;       Added Tom Groetzinger's macro definitions.
0000     90 ;
0000     91 ; 02    Dave Spain      30 Jan 80
0000     92 ;       Added Tony Vezza's macro definitions.
0000     93 ;
0000     94 ; 01    Dave Spain      29 Jan 80
0000     95 ;       Macros initiated.

                        001C      5 ;
                        001C      6 ; FUNCTIONAL DESCRIPTION
                        001C      7 ;
                        001C      8 ;       This test examines the BUT/CM.ODD.ADD micro-order for proper operation.
                        001C      9 ;       The BUT/CM.ODD.ADD micro-order will force a one into CSA<0> when VA<0>
                        001C     10 ;       is a one and D Size is Byte.
                        001C     11 ;
                        001C     12 ;
                        001C     13 ; TEST ALGORITHM
                        001C     14 ;
                        001C     15 ;       To fully test the BUT/CM.ODD.ADD micro-order all four combinations of
                        001C     16 ;       VA<0> and D Size equal to byte should be tried. This test has been
                        001C     17 ;       divided into four subtests. Each trys a different combination of VA<0>
                        001C     18 ;       and D Size equal to byte.
                        001C     19 ;
                        001C     20 ;       The test is implemented by the following algorithm:
                        001C     21 ;
                        001C     22 ;       Subtest 1
                        001C     23 ;
                        001C     24 ;       This subtest loads the VA with 0, the IR with a MOVB instruction and
                        001C     25 ;       expects a 0 in CSA<0> during the BUT/CM.ODD.ADD micro-branch.
                        001C     26 ;
                        001C     27 ;        1. Initialize the CPU.
                        001C     28 ;        2. Open the window to the signature analyzer.
                        001C     29 ;        3. Execute the following micro-code to set up the test:
                        001C     30 ;                1. Place the CPU into compatibility mode.
                        001C     31 ;                2. Disable console CTRL-P interrupts from occuring.
                        001C     32 ;                3. Zero the VA.
                        001C     33 ;                4. Write the test opcodes to cache for XB0.
                        001C     34 ;                5. Increment the VA.
                        001C     35 ;                6. Write zeroes into the next cache location for XB1.
                        001C     36 ;                7. Zero the VA.
                        001C     37 ;                8. Zero the PC to initiate instruction prefetch.
                        001C     38 ;                9. Load the IR and the OSR with the first test opcode.
                        001C     39 ;        4. Prepare the RDM to expect any control store address.
                        001C     40 ;        5. Loop on error from here.
                        001C     41 ;        6. Execute a BUT/CM.ODD.ADD micro-branch with 1800 in the NEXT field.
                        001C     42 ;        7. Using a mask of 3FFF compare the Control Store address TRaP
                        001C     43 ;           register (CSTRP) with the expected result of 1800.
                        001C     44 ;        8. Execute micro-code to write the IR and OSR into RTEMP0 and to write
                        001C     45 ;           the current value of the VA to RTEMP1:
                        001C     46 ;                10. Write the IR into the MDR.
                        001C     47 ;                11. Write an eight into the P-LATCH on the rotator.
                        001C     48 ;                12. Shift the MDR left 8 bits and store the result into RTEMP0.
                        001C     49 ;                13. Write the OSR into the MDR.
                        001C     50 ;                14. OR the MDR with RTEMP0 and store the result in RTEMP0.
                        001C     51 ;                15. Write the VA into RTEMP1.
                        001C     52 ;        9. If the address in the Control Store address TRaP register (CSTRP)
                        001C     53 ;           is not 1800, signal an error and dump out RTEMP0 and RTEMP1.
                        001C     54 ;
                        001C     55 ;       Subtest 2
                        001C     56 ;
                        001C     57 ;       This subtest loads the VA with 1, keeps the MOVB instruction in the IR,
                        001C     58 ;       and expects a 0 in CSA<0> during the BUT/CM.ODD.ADD micro-branch.
```

```
001C     59 ;
001C     60 ;       10. Execute the micro-code to load VA<0> with a one.
001C     61 ;       11. Prepare the RDM to expect any control store address.
001C     62 ;       12. Loop on error from here.
001C     63 ;       13. Execute the BUT/CM.ODD.ADD branch using the same opcode.
001C     64 ;       14. Do a masked comparison of the CSTRP register against 1800.
001C     65 ;       15. Write the IR and OSR to RTEMP0 and the VA to RTEMP1.
001C     66 ;       16. If the control store address was not 1800 signal an error.
001C     67 ;

0019          .SBTTL  "TEST   OCF     CM IR2.TO.0 BUT Test
0019    398 ;*****************************************************************************
0019    399 ;++
0019    400 ;
0019    401 ; FUNCTIONAL DESCRIPTION
0019    402 ;
0019    403 ;       This test examines the BUT/IR2.TO.0 micro-branch while the CPU is in
0019    404 ;       compatibility mode. This will insure that the micro-branch is still
0019    405 ;       done on IR<2:0> even when the CPU is in compatibility mode.
0019    406 ;
0019    407 ; TEST ALGORITHM
0019    408 ;
0019    409 ;       This test is implemented by running through all eight combinations of
0019    410 ;       IR<2:0>. The steps required are:
0019    411 ;
0019    412 ;        1. Initialize the CPU.
0019    413 ;        2. Open the window to the signature analyzer.
0019    414 ;        3. Tell the RDM to expect any control store address.
0019    415 ;        4. Execute micro-code to put the CPU into compatibility mode and to
0019    416 ;           disable console Control-P interrupts.
0019    417 ;        5. Initialize the WD register to zero.
0019    418 ;        6. Loop for all combinations of IR<2:0>. (8 iterations)
0019    419 ;        7. Load the WD register with a model opcode indexed by the loop count.
0019    420 ;        8. Execute the following micro-code to set up the test:
0019    421 ;                1. Write the model opcode from the WD register to RTEMP0.
0019    422 ;                2. Zero the VA.
0019    423 ;                3. Write the model opcode from RTEMP0 to cache.
0019    424 ;                4. Increment the VA.
0019    425 ;                5. Zero the next cache location for XB1.
0019    426 ;                6. Zero the PC to initiate instruction prefetch.
0019    427 ;                7. Load the IR and OSR using a BUT/IRD1TST micro-order.
0019    428 ;        9. Loop on error from here.
0019    429 ;       10. Execute the BUT/IR2.TO.0 micro-branch with 1800 in the NEXT field.
0019    430 ;       11. Compare (masked) the expected and received control store addresses.
0019    431 ;       12. Execute the micro-code to place the IR and OSR into RTEMP0.
0019    432 ;       13. If the addresses are not equal signal and error and dump RTEMP0.
0019    433 ;       14. Continue the loop until every combination of IR<2:0> is tried.
0019    434 ;       15. Execute the micro-code to put CPU back into native mode and to
0019    435 ;           enable console Control-P interrupts.
0019    436 ;       16. Close the window to the signature analyzer.
0019    437 ;       17. End of test.
0019    438 ;

0014    679 ;*****************************************************************************
0014    680 ;++
0014    681 ;
0014    682 ; FUNCTIONAL DESCRIPTION
0014    683 ;
0014    684 ;       This test will examine the BUT/IR2 micro-branch the CPU is in
0014    685 ;       compatibility mode for proper operation.
0014    686 ;
0014    687 ; TEST ALGORITHM
0014    688 ;
0014    689 ;       Because the BUT/IR2 micro-branch actually uses CIR<2>, the opcode
0014    690 ;       bits used will be different depending on the class of the instruction
0014    691 ;       being decoded. To fully examine the micro-branch, this test will loop
0014    692 ;       until all the different opcodes have been tried.
0014    693 ;
0014    694 ;       The steps used are as follows:
0014    695 ;
0014    696 ;        1. Initialize the CPU.
0014    697 ;        2. Open the window to the signature analyzer.
0014    698 ;        3. Execute micro-code to place the CPU into compatibility mode and
0014    699 ;           to disable console Control-P interrupts.
0014    700 ;        4. Initialize the WD Register with a lonword of zero.
0014    701 ;        5. Loop for all IR2 decodes. (12 iterations)
0014    702 ;        6. Load an opcode from a table indexed by the loop count into WDREG.
0014    703 ;        7. Execute micro-code to move the opcode from the WDREG to RTEMP0.
0014    704 ;        8. Loop on error from here.
0014    705 ;        9. Execute the BUT/IR2 micro-branch, with 1800 in the NEXT field.
0014    706 ;       10. Do a masked comarison of the address in the Control Store address
0014    707 ;           TRaP register (CSTRP) with the expected address.
0014    708 ;       11. Execute micro-code to read back the contents of the IR and OSR.
0014    709 ;       12. If the expected and received control store addresses are not equal,
0014    710 ;           signal an error.
0014    711 ;       13. Otherwise continue the loop for all the opcodes.
0014    712 ;       14. Execute micro-code to enable console Control-P interrupts and to
0014    713 ;           return the CPU to native mode.
0014    714 ;       15. Close the window to the signature analyzer.
0014    715 ;       16. End of test.
0014    716 ;
0014    717 ; TEST DATA
0014    718 ;
0014    719 ;       Below is a table of the opcodes, expected control store addresses,
0014    720 ;       opcode values for CIR<2>, instruction mnemonic and class used for
0014    721 ;       each loop iteration of the test. Note that OPCODE bits are the same
0014    722 ;       as XB0 bits for this test.

                        0014   748 ;
                        0014   749 ;       In this test the micro-branch is executed by driving CIR<2> onto bit 0
                        0014   750 ;       of the control store address. (CSA<0>) CSA<0> is determined by three
                        0014   751 ;       things; discrete logic on the DPM, the IRD gate array, and the PHB
                        0014   752 ;       gate array. CSA<0> is generated by an inverter that sits on the output
                        0014   753 ;       of an 8 to 1 multiplexer. The mux is enabled by the signal ENABLE BUT
                        0014   754 ;       4XXX, which is generated by a 1 of 8 decoder whose select lines depend
                        0014   755 ;       upon bits 5:3 of the BUT field. For the BUT/IR2 micro-order, input D2
                        0014   756 ;       is selected. This input comes directly from IR<2> on the IRD chip.
                        0014   757 ;       The selection of CIR<2> as opposed to IR<2> is determined by the IRD
                        0014   758 ;       gate array. IRD in turn uses the control signals IRD ADD CTL 1 and
                        0014   759 ;       IRD ADD CTL 0 from the PHB gate array.
                        0014   760 ;
                        0014   761 ; ASSUMPTIONS

0014          .SBTTL  "TEST   0D1     CM IR5 BUT Test
0014    961 ;*****************************************************************************
0014    962 ;++
0014    963 ;
0014    964 ; FUNCTIONAL DESCRIPTION
0014    965 ;
0014    966 ;       This test examines a compatibility mode BUT/IR5 micro-branch.
0014    967 ;       For compatibility mode the BUT/IR5 micro-branch is executed on CIR<5>.
0014    968 ;       Since CIR<5> is a decode of the instruction in the IR its value will
0014    969 ;       depend upon the class of the instruction as defined in Chart 4.4.1A
0014    970 ;       of the micro-sequencer specification.
0014    971 ;
0014    972 ; TEST ALGORITHM
0014    973 ;
0014    974 ;       To obtain all the CIR decodes this test has been divided into
0014    975 ;       six subtests. Each subtest trys a different instruction class for
0014    976 ;       CIR<5>.
0014    977 ;
0014    978 ;       Subtest 1
0014    979 ;
0014    980 ;       This subtest examines the micro-branch for a Class A instruction.
0014    981 ;       According to Chart 4.4.1A, a Class A instruction decodes CIR<5> using
0014    982 ;       OPCODE<8>. Therefore, this subtest will loop for two iterations,
0014    983 ;       toggling OPCODE<8>. OPCODE<8> is the same as XB0<8>.
0014    984 ;
0014    985 ;       Subtests 2 - 6
0014    986 ;
0014    987 ;       These subtests examine the micro-branch for the remaining classes of
0014    988 ;       compatiblity mode instructions. Since these classes force CIR<5> to
0014    989 ;       either a 1 or a 0, only one pass is needed through each subtest.
0014    990 ;
0014    991 ;       Here are the steps used to implement the subtests. Note that Subtest 1
0014    992 ;       will loop twice between steps 5 and 11 in order to toggle OPCODE<8>.
0014    993 ;
0014    994 ;         1. Initialize the CPU.
0014    995 ;         2. Open the window to the signature analyzer.
0014    996 ;         3. Execute the micro-code to place the CPU into compatibility mode and
0014    997 ;            to disable console Control-P interrupts so that the micro-branch
0014    998 ;            will not trap.
0014    999 ;         4. Initialize the WD Register on the RDM with a longword of zeros.
0014   1000 ;         5. Load a test opcode into the WD register on the RDM.
0014   1001 ;         6. Execute micro-code to write the test opcode from the WD register to
0014   1002 ;            the IR and OSR in the CPU.
0014   1003 ;         7. Loop on error from here.
0014   1004 ;         8. Execute the BUT/IR5 micro-branch with 1800 in the NEXT field so
0014   1005 ;            that the RDM will allow the branch to finish.
0014   1006 ;         9. Do a masked comparison of the address generated by the micro-branch
0014   1007 ;            against the expected address.
0014   1008 ;        10. Execute the micro-code to read the IR and OSR into RTEMP0.
0014   1009 ;        11. If the micro-branch and expected addresses are different, signal an
0014   1010 ;            error and dump out RTEMP0.
0014   1011 ;
0014   1012 ; TEST DATA
0014   1013 ;
0014   1014 ;       This table gives the expected control store address, and instruction
0014   1015 ;       opcode, mnemonic and class for each subtest.
0014   1016 ;

0014  1025 ;
0014  1026 ;       This table gives the initial value of the RTEMP registers used.
0014  1027 ;
0014  1028 ;       RTEMP0 = 0                  Current opcode in the IR and OSR.
0014  1029 ;       RTEMP1 = ^X80000000         Data to place CPU into compatibility mode.
0014  1030 ;       RTEMP2 = ^X00C00000         Address of status and control bit in CRAR.
0014  1031 ;       RTEMP3 = ^X00400000         Data to disable console Control-P interrupts.
0014  1032 ;       RTEMP4 = ^X00900000         Data to enable console Control-P interrupts.
0014  1033 ;
0014  1034 ; LOGICAL DESCRIPTION
0014  1035 ;
0014  1036 ;       In this test the micro-branch is executed by ORing CIR<5> in bit 0 of
0014  1037 ;       the control store address (CSA<0>). CSA<0> is determined by three
0014  1038 ;       things; discrete logic on the DPM, the IRD gate array, and the PHB
0014  1039 ;       gate array. CSA<0> is generated by an inverter that sits on the output
0014  1040 ;       of an 8 to 1 multiplexer. The mux is enabled by the signal ENABLE BUT
0014  1041 ;       4XXX, which is generated by a 1 of 8 decoder whose select lines depend
0014  1042 ;       upon bits 5:3 of the BUT field. For the BUT/IR5 micro-order, input D3
0014  1043 ;       is selected. This input comes directly from IR<5> on the IRD chip.
0014  1044 ;       The selection of CIR<5> as opposed to IR<5> is determined by the IRD
0014  1045 ;       gate array. IRD in turn uses the control signals IRD ADD CTL 1 and
0014  1046 ;       IRD ADD CTL 0 from the PHB gate array.
0014  1047 ;
0014  1048 ; ASSUMPTIONS
0014  1049 ;
0014  1050 ;       This test assumes the following logic is working; the VA, PC, RTEMPS,
0014  1051 ;       ALU, ROTATOR, and the IR and OSR.
0014  1052 ;
0014  1053 ; ERROR DESCRIPTION
0014  1054 ;
0014  1055 ;       One error this test calls out the IRD and PHB gate arrays on the DPM.
0014  1056 ;       The following information is also typed out:
0014  1057 ;
0014  1058 ;       Subtest 1
0014  1059 ;

                        001E  1357 ;         1. Initialize the CPU.
                        001E  1358 ;         2. Open the window for the signature analyzer.
                        001E  1359 ;         3. Execute micro-code to:
                        001E  1360 ;                 1. Set the compatibility mode bit in the PSL.
                        001E  1361 ;                 2. Disable a console CTRL-P interrupt after a BUT micro-order.
                        001E  1362 ;         4. Initialize the WD register with zero.
                        001E  1363 ;         5. Set up to expect non-DCS addresses.
                        001E  1364 ;         6. Prepare a loop for all possible offsets. (17 iterations)
                        001E  1365 ;         7. Load the test opcode into the RDM WD register.
                        001E  1366 ;         8. Execute the following micro-code to set up the test:
                        001E  1367 ;                 3. Load the model opcode from the WDREG to RTEMP0.
                        001E  1368 ;                 4. Write RTEMP0 to cache at physical location 0.
                        001E  1369 ;                 5. Increment the VA by 4.
                        001E  1370 ;                 6. Write a longword a zeroes to cache to validate it for
                        001E  1371 ;                    instruction prefetch.
                        001E  1372 ;                 7. Load the PC with zero to initiate instruction prefetch.
                        001E  1373 ;                 8. Execute a BUT/IRD1TST to load the IR and OSR.
                        001E  1374 ;         9. Loop on error from this point.
                        001E  1375 ;        10. Execute the following test micro-code:
                        001E  1376 ;                 9. NEXT/1800,BUT/BRA.ON.ADD
                        001E  1377 ;        11. Do a masked comparison of the address in the Control Store Address
                        001E  1378 ;            Trap register with the expected control store address.
                        001E  1379 ;        12. Execute micro-code to:
                        001E  1380 ;                10. Place the zero extended contents of the IR into the MDR.
                        001E  1381 ;                11. Rotate the MDR left by 8 bits and put it into RTEMP0.
                        001E  1382 ;                12. Place the zero extended contents of the OSR into the MDR.
                        001E  1383 ;                13. Or the MDR with RTEMP0 and put the results into RTEMP0.
                        001E  1384 ;        13. If the expected and received control store addresses were different
                        001E  1385 ;            signal an error and dump out the contents of the IR and OSR that
                        001E  1386 ;            were placed in RTEMP0.
                        001E  1387 ;        14. Continue the loop started in step 6.
                        001E  1388 ;        15. Execute micro-code to:
                        001E  1389 ;                14. Enable CTRL-P interrupts after a BUT micro-order.
                        001E  1390 ;                15. Zero out the PSL to restore native mode.
                        001E  1391 ;        16. Close the window to the signature analyzer.
                        001E  1392 ;        17. End of test.
                        001E  1393 ;

001E  1424 ; LOGICAL DESCRIPTION
001E  1425 ;
001E  1426 ;       The logic involved in the branch on address micro-order is contained
001E  1427 ;       inside the IRD and PHB gate arrays. For this test the control store
001E  1428 ;       addresses generated will depend on the second operand specifier which
001E  1429 ;       has been loaded into the OSR, the micro-order itself, and the control
001E  1430 ;       signals IRD ADD CTL1, IRD ADD CTL 0 and PSL CM which come from the PHB
001E  1431 ;       gate array.
001E  1432 ;
001E  1433 ; ASSUMPTIONS
001E  1434 ;
001E  1435 ;       This test assumes the following logic has been tested prior to the
001E  1436 ;       execution of this test. The RTEMP registers, and the IR and OSR.
001E  1437 ;
001E  1438 ; ERROR DESCRIPTION
001E  1439 ;
001E  1440 ;       On error this test will call out the IRD and PHB gate arrays and
001E  1441 ;       the following information:
001E  1442 ;
001E  1443 ;       EXPECTED CONTROL STORE ADDRESS
001E  1444 ;       RECEIVED CONTROL STORE ADDRESS
001E  1445 ;       LOOP COUNT
001E  1446 ;       OPCODE OF THE INSTRUCTION BEING DECODED

0016  1632 ;*******************************************************************************
0016  1633 ;++
0016  1634 ;
0016  1635 ; FUNCTIONAL DESCRIPTION
0016  1636 ;
0016  1637 ;       This test examines all of the mode bits in a compatibility mode operand
0016  1638 ;       specifier for all possible control store address offsets. The addresses
0016  1639 ;       generated are checked against chart 4.1.3B in the micro-sequencer spec.
0016  1640 ;
0016  1641 ; TEST ALGORITHM
0016  1642 ;
0016  1643 ;       The algorithm used to implement this test is as follows:
0016  1644 ;
0016  1645 ;         1. Initialize the CPU.
0016  1646 ;         2. Open the window to the signature analyzer.
0016  1647 ;         3. Execute the micro-code to put the CPU into compatibility mode.
0016  1648 ;         4. Prepare the RDM to expect non-DCS addresses.
0016  1649 ;         5. Initialize the WD register with zero.
0016  1650 ;         6. Prepare a loop for all operand modes. (17 iterations)
0016  1651 ;         7. Load a model opcode into the WD register.
0016  1652 ;         8. Loop on error from here.
0016  1653 ;         9. Execute the test micro-code:
0016  1654 ;                 1. Write the model opcode from WDREG to RTEMP0.
0016  1655 ;                 2. Zero the VA.
0016  1656 ;                 3. Write the model opcode to cache.
0016  1657 ;                 4. Increment the VA.
0016  1658 ;                 5. Write zero to cache to validate location for XB1.
0016  1659 ;                 6. Zero the PC to initiate instruction prefetch.
0016  1660 ;                 7. Execute a BUT/IRD1 to decode the instruction.
0016  1661 ;        10. Mask the address in the Control Store address TRaP register (CSTRP)
0016  1662 ;            and compare it to the expected address for the current iteration.
0016  1663 ;        11. Execute micro-code to read back the IR and OSR:
0016  1664 ;                 8. Load the MDR with the IR zero extended.
0016  1665 ;                 9. Load an 8 into the rotator's P-LATCH.
0016  1666 ;                10. Shift the MDR left 8 bits and load it into RTEMP0.
0016  1667 ;                11. Load the MDR with the OSR zero extended.
0016  1668 ;                12. OR the MDR with RTEMP0 and store the results into RTEMP0.
0016  1669 ;        12. If CSTRP does not equal the expected address, signal an error and
0016  1670 ;            dump out RTEMP0.
0016  1671 ;        13. Continue the loop for all modes.
0016  1672 ;        14. Execute the micro-code to place the CPU back into native mode.
0016  1673 ;        15. Close the window to the signature analyzer.
0016  1674 ;        16. End of test
0016  1675 ;
0016  1676 ; TEST DATA
0016  1677 ;
0016  1678 ;       Only the first operand of the two operand MOV instruction is used.

                        002E  2735 ;       This test is executed in the following manner:
                        002E  2736 ;
                        002E  2737 ;        1. Initialize the CPU.
                        002E  2738 ;        2. Execute the micro-code to place the CPU into compatibility mode.
                        002E  2739 ;        3. Initialize the WD register with zero.
                        002E  2740 ;        4. Prepare a loop for 256 instructions.
                        002E  2741 ;        5. Load the WD register with a model opcode from the first table
                        002E  2742 ;           indexed by the loop count.
                        002E  2743 ;        6. Execute the micro-code to:
                        002E  2744 ;                1. Load RTEMP1 with the data from the WD register.
                        002E  2745 ;                2. Load the VA with zero.
                        002E  2746 ;                3. Write the model instruction from RTEMP1 to cache.
                        002E  2747 ;                4. Increment the VA for the next address.
                        002E  2748 ;                5. Write zeros into this cache location to prevent cache
                        002E  2749 ;                   parity errors from trapping the IRD1 decode.
                        002E  2750 ;                6. Zero the PC which will initiate instruction prefetch.
                        002E  2751 ;                7. Execute a BUT/IRD1.
                        002E  2752 ;                8. Halt.
                        002E  2753 ;        7. Execute a masked comparison of the control store address trace
                        002E  2754 ;           register with the expected CS address.
                        002E  2755 ;        8. If the two are different signal an error.
                        002E  2756 ;        9. Otherwise continue looping from step 4 to step 8 till all 256
                        002E  2757 ;           instructions have been decoded.
                        002E  2758 ;       10. Execute the micro-code to place the CPU back into native mode.
                        002E  2759 ;       11. Exit.
                        002E  2760 ;
                        002E  2761 ; DATA PATTERNS
                        002E  2762 ;
                        002E  2763 ;       The input data patterns were derived from chapter 4.4 of the CPU
                        002E  2764 ;       micro-sequencer specification dated on 9/25/78. Because operand
                        002E  2765 ;       specifiers are embedded into compatibility mode instructions, certain
                        002E  2766 ;       instructions have more than one opcode decode. Model opcodes were
                        002E  2767 ;       generated by first using Chart 4.4.1B to obtain the base opcodes for
                        002E  2768 ;       each compatibility mode instruction. These opcodes were then enhanced
                        002E  2769 ;       to include all the possible decodes. The enhancements were obtained
                        002E  2770 ;       by changing the operands to specify both register and non-register
                        002E  2771 ;       modes and by using Chart 4.4.1A to modify the operands to get all
                        002E  2772 ;       possible instruction decodes.
                        002E  2773 ;
                        002E  2774 ;       The expected control store addresses where obtained from the
                        002E  2775 ;       Compatibility Mode Ird Rom Definition in the CPU micro-code.
                        002E  2776 ;
                        002E  2777 ;       The following is a table that shows the compatibility mode instruction
```

```
002E  2778 ;       being decoded for a corresponding range of loop counts:
002E  2779 ;

                        002E  3108 ;
                        002E  3109 ;       This test makes sure the proper control store addresses are generated
                        002E  3110 ;       for compatiblity mode IRD1s. The test is implemented by using two
                        002E  3111 ;       data tables. The first table consists of assembled VAX compatibility
                        002E  3112 ;       mode macro instructions. The second table consists of expected control
                        002E  3113 ;       store addresses for the IRD1. This test executes those instructions
                        002E  3114 ;       which could not be decoded in test one due to RDM memory contraints.
                        002E  3115 ;
                        002E  3116 ; TEST ALGORITHM
                        002E  3117 ;
                        002E  3118 ;       This test is executed in the following manner:
                        002E  3119 ;
                        002E  3120 ;        1. Initialize the CPU.
                        002E  3121 ;        2. Execute the micro-code to place the CPU into compatibility mode.
                        002E  3122 ;        3. Initialize the WD register with zero.
                        002E  3123 ;        4. Prepare a loop for 28 instructions.
                        002E  3124 ;        5. Load the WD register with a model opcode from the first table
                        002E  3125 ;           indexed by the loop count.
                        002E  3126 ;        6. Execute the micro-code to:
                        002E  3127 ;                1. Load RTEMP1 with the data from the WD register.
                        002E  3128 ;                2. Load the VA with zero.
                        002E  3129 ;                3. Write the model instruction from RTEMP1 to cache.
                        002E  3130 ;                4. Increment the VA for the next address.
                        002E  3131 ;                5. Write zeros into this cache location to prevent cache
                        002E  3132 ;                   parity errors from trapping the IRD1 decode.
                        002E  3133 ;                6. Zero the PC which will initiate instruction prefetch.
                        002E  3134 ;                7. Execute a BUT/IRD1.
                        002E  3135 ;                8. Halt.
                        002E  3136 ;        7. Execute a masked comparison of the control store address trace
                        002E  3137 ;           register with the expected CS address.
                        002E  3138 ;        8. If the two are different signal an error.
                        002E  3139 ;        9. Otherwise continue looping from step 4 to step 8 till finished.
                        002E  3140 ;       10. Execute the micro-code to place the CPU back into native mode.
                        002E  3141 ;       11. Exit.
                        002E  3142 ;
                        002E  3143 ; DATA PATTERNS
                        002E  3144 ;
                        002E  3145 ;       The input data patterns were derived from chapter 4.4 of the CPU
                        002E  3146 ;       micro-sequencer specification dated on 9/25/78. Because operand
                        002E  3147 ;       specifiers are embedded into compatibility mode instructions, certain
                        002E  3148 ;       instructions have more than one opcode decode. Model opcodes were
                        002E  3149 ;       generated by first using Chart 4.4.1B to obtain the base opcodes for
                        002E  3150 ;       each compatibility mode instruction. These opcodes were then enhanced
                        002E  3151 ;       to include all the possible decodes. The enhancements were obtained
                        002E  3152 ;       by changing the operands to specify both register and non-register
                        002E  3153 ;       modes and by using Chart 4.4.1A to modify the operands to get all
                        002E  3154 ;       possible instruction decodes.
                        002E  3155 ;
                        002E  3156 ;       The expected control store addresses where obtained from the
                        002E  3157 ;       Compatibility Mode Ird Rom Definition in the CPU micro-code.
                        002E  3158 ;
                        002E  3159 ;       The following is a table that shows the instruction being decoded for
```

0034  3386 ;*****************************************************************************
0034  3387 ;++
0034  3388 ;
0034  3389 ; FUNCTIONAL DESCRIPTION
0034  3390 ;
0034  3391 ;       This test makes sure the proper control store addresses are generated
0034  3392 ;       for the first compatiblity mode IRDX. The test is implemented by using
0034  3393 ;       two data tables. The first table consists of assembled VAX compatibil-
0034  3394 ;       ity mode macro instructions. The second table consists of expected
0034  3395 ;       control store addresses for the first IRDX.
0034  3396 ;
0034  3397 ; TEST ALGORITHM
0034  3398 ;
0034  3399 ;       This test is executed in the following manner:
0034  3400 ;
0034  3401 ;        1. Initialize the CPU.
0034  3402 ;        2. Execute micro-code to place the CPU into compatibility mode,
0034  3403 ;           disable the console CTRL-P interrupt and zeroes the MDR in order
0034  3404 ;           to allow the IRDX to function.
0034  3405 ;        3. Initialize the WD register with zero.
0034  3406 ;        4. Prepare a loop for 28 instructions.
0034  3407 ;        5. Load the WD register with a model opcode from the opcode table
0034  3408 ;           indexed by the loop count.
0034  3409 ;        6. Execute the micro-code to:
0034  3410 ;                1. Load an RTEMP with the data from the WD register.
0034  3411 ;                2. Load the VA with zero.
0034  3412 ;                3. Write the model instruction from RTEMP to cache.
0034  3413 ;                4. Increment the VA for the next address.
0034  3414 ;                5. Write zeros into this cache location to prevent cache
0034  3415 ;                   parity errors from trapping the IRD1 decode.
0034  3416 ;                6. Zero the PC which will initiate instruction prefetch.
0034  3417 ;                7. Execute a BUT/IRD1TST to load the IR and OSR.
0034  3418 ;                8. Execute a BUT/IRDX.
0034  3419 ;                9. Halt.
0034  3420 ;        7. Execute a masked comparison of the control store address trace
0034  3421 ;           register with the expected CS address.
0034  3422 ;        8. If the two are different signal an error.
0034  3423 ;        9. Otherwise continue looping from step 4 to step 8 till finished.
0034  3424 ;       10. Execute the micro-code to place the CPU back into native mode
0034  3425 ;           and enable the console CTRL-P interrupt.
0034  3426 ;       11. Exit.
0034  3427 ;
0034  3428 ; DATA PATTERNS
0034  3429 ;
0034  3430 ;       The input data patterns were derived from chapter 4.4 of the CPU
0034  3431 ;       micro-sequencer specification dated on 9/25/78. Because operand
0034  3432 ;       specifiers are embedded into compatibility mode instructions, certain
0034  3433 ;       instructions have more than one opcode decode. Model opcodes were
0034  3434 ;       generated by first using Chart 4.4.1B to obtain the base opcodes for
0034  3435 ;       each compatibility mode instruction. These opcodes were then enhanced
0034  3436 ;       to include all the possible decodes. The enhancements were obtained
0034  3437 ;       by changing the operands to specify both register and non-register
0034  3438 ;       modes and by using Chart 4.4.1A to modify the operands to get all
0034  3439 ;       possible instruction decodes.
0034  3440 ;
0034  3441 ;       The expected control store addresses where obtained from the
```

```
0034  3442 ;       Compatibility Mode Ird Rom Definition in the CPU micro-code.
0034  3443 ;
0034  3444 ;       The following is a table that shows the instruction being decoded for
0034  3445 ;       a range of loop counts:
0034  3446 ;
0034  3447 ;       NOTE! - This table is NOT the same as that for CM IRD1.
0034  3448 ;

0034          .SBTTL  "TEST   0D9     CM First IRDX Instruction Address Decode Test 2
0034  3797 ;*****************************************************************************
0034  3798 ;++
0034  3799 ;
0034  3800 ; FUNCTIONAL DESCRIPTION
0034  3801 ;
0034  3802 ;       This test makes sure the proper control store addresses are generated
0034  3803 ;       for the first compatiblity mode IRDX. The test is implemented by using
0034  3804 ;       two data tables. The first table consists of assembled VAX compatibil-
0034  3805 ;       ity mode macro instructions. The second table consists of expected
0034  3806 ;       control store addresses for the first IRDX. This test decodes those
0034  3807 ;       instructions not done in test one due to insufficient RDM memory space.
0034  3808 ;
0034  3809 ; TEST ALGORITHM
0034  3810 ;
0034  3811 ;       This test is executed in the following manner:
0034  3812 ;
0034  3813 ;        1. Initialize the CPU.
0034  3814 ;        2. Execute micro-code to place the CPU into compatibility mode,
0034  3815 ;           disable the console CTRL-P interrupt and zeroes the MDR in order
0034  3816 ;           to allow the IRDX to function.
0034  3817 ;        3. Initialize the WD register with zero.
0034  3818 ;        4. Prepare a loop for 30 instructions.
0034  3819 ;        5. Load the WD register with a model opcode from the opcode table
0034  3820 ;           indexed by the loop count.
0034  3821 ;        6. Execute the micro-code to:
0034  3822 ;                1. Load RTEMP1 with the data from the WD register.
0034  3823 ;                2. Load the VA with zero.
0034  3824 ;                3. Write the model instruction from RTEMP1 to cache.
0034  3825 ;                4. Increment the VA for the next address.
0034  3826 ;                5. Write zeros into this cache location to prevent cache
0034  3827 ;                   parity errors from trapping the IRD1 decode.
0034  3828 ;                6. Zero the PC which will initiate instruction prefetch.
0034  3829 ;                7. Execute a BUT/IRD1TST to load the IR and OSR.
0034  3830 ;                8. Execute a BUT/IRDX.
0034  3831 ;                9. Halt.
0034  3832 ;        7. Execute a masked comparison of the control store address trace
0034  3833 ;           register with the expected CS address.
0034  3834 ;        8. If the two are different signal an error.
0034  3835 ;        9. Otherwise continue looping from step 4 to step 8 till finished.
0034  3836 ;       10. Execute the micro-code to place the CPU back into native mode
0034  3837 ;           and enable the console CTRL-P interrupt.
0034  3838 ;       11. Exit.
0034  3839 ;
0034  3840 ; DATA PATTERNS
0034  3841 ;
0034  3842 ;       The input data patterns were derived from chapter 4.4 of the CPU
0034  3843 ;       micro-sequencer specification dated on 9/25/78. Because operand
0034  3844 ;       specifiers are embedded into compatibility mode instructions, certain
0034  3845 ;       instructions have more than one opcode decode. Model opcodes were
0034  3846 ;       generated by first using Chart 4.4.1B to obtain the base opcodes for
0034  3847 ;       each compatibility mode instruction. These opcodes were then enhanced
0034  3848 ;       to include all the possible decodes. The enhancements were obtained
0034  3849 ;       by changing the operands to specify both register and non-register
0034  3850 ;       modes and by using Chart 4.4.1A to modify the operands to get all
0034  3851 ;       possible instruction decodes.
0034  3852 ;
```

```
0034  3853 ;       The expected control store addresses where obtained from the
0034  3854 ;       Compatibility Mode Ird Rom Definition in the CPU micro-code.
0034  3855 ;
0034  3856 ;       The following is a table that shows the instruction being decoded for
0034  3857 ;       a range of loop counts:
0034  3858 ;
0034  3859 ;       NOTE! - This table is NOT the same as that for CM IRD1.
0034  3860 ;
0034  3861 ;       Loop            Instruction
0034  3862 ;
0034  3863 ;       01              BISB
0034  3864 ;       02 - 05         SUB
0034  3865 ;       06 - 0D         JMP
0034  3866 ;       0E              RTS
0034  3867 ;       0F - 10         (unused)
0034  3868 ;       11              SPL
0034  3869 ;       12              NOP
0034  3870 ;       13 - 16         (reserved)
0034  3871 ;       17 - 1E         SWAB
0034  3872 ;
0034  3873 ; LOGICAL DESCRIPTION
0034  3874 ;
0034  3875 ;       During an IRD1 in compatibility mode the CCS ROMs are fed addresses
0034  3876 ;       from the Compatibility Mode IRD1 and IRDX ROMs on the DPM. The DPM ROMs
0034  3877 ;       are addressed according to the following scheme:
0034  3878 ;
0034  3879 ;       Source          ROM Address Bits        Comment
0034  3880 ;
0034  3881 ;       CIR <7:0>       <10:3>                  Encoded opcode generated by the
0034  3882 ;                                               IRD gate array.
0034  3883 ;
0034  3884 ;       IRD1            <2>                     Distinguishes between the 1st
0034  3885 ;                                               operand and the 2nd operand or

0035        .SBTTL  "TEST   0DA     CM Second IRDX Instruction Address Decode Test 1
0035  4112 ;*******************************************************************************
0035  4113 ;++
0035  4114 ;
0035  4115 ; FUNCTIONAL DESCRIPTION
0035  4116 ;
0035  4117 ;       This test makes sure the proper control store addresses are generated
0035  4118 ;       for the second compatiblity mode IRDX. The test is implemented by using
0035  4119 ;       two data tables. The first table consists of assembled VAX compatibil-
0035  4120 ;       ity mode macro instructions. The other table consists of expected
0035  4121 ;       control store addresses for the second IRDX.
0035  4122 ;
0035  4123 ; TEST ALGORITHM
0035  4124 ;
0035  4125 ;       The IRDX micro-order will assert addresses onto the CS address bus
0035  4126 ;       which will cause the RDM to stop the processor clock. Thus if the first
0035  4127 ;       IRDX is executed using the FETCH and BRSTCLK pseudo-ops, the clock will
0035  4128 ;       stop before the IRDX is finished. This causes bad addresses to be
0035  4129 ;       generated for some of the macro instructions being decoded. To prevent
0035  4130 ;       this from happening, the LOADREG pseudo-op is used to execute the
0035  4131 ;       micro-code that fetches the macro instructions, loads the IR and OSR
0035  4132 ;       and does the first IRDX. The second IRDX can be executed using the
0035  4133 ;       FETCH and BRSTCLK pseudo-ops since the address that is generated will
0035  4134 ;       not depend on whether that micro-order finishes execution.
0035  4135 ;
0035  4136 ;       This test is executed in the following manner:
0035  4137 ;
0035  4138 ;        1. Initialize the CPU.
0035  4139 ;        2. Execute micro-code to place the CPU into compatibility mode,
0035  4140 ;           disable the console CTRL-P interrupt and zero the MDR in order
0035  4141 ;           to allow the IRDX to function.
0035  4142 ;        3. Initialize the WD register with zero.
0035  4143 ;        4. Prepare a loop for 239 instructions.
0035  4144 ;        5. Load the WD register with a model opcode from the opcode table
0035  4145 ;           indexed by the loop count.
0035  4146 ;        6. Take the CPU off the CS address bus and hold the CPU clock
0035  4147 ;           off by setting the bits uADINH, CLKCN1, CLKCN0, PARSTP, and PARCHK
0035  4148 ;           in the DCS Control Register (DCSCR).
0035  4149 ;        7. Load the DCS Address Counter (DCSAD) with the starting location of
0035  4150 ;           the test micro-code.
0035  4151 ;        8. Load the Control Store Address Match Register (CSAMR) with the
0035  4152 ;           starting address of the test micro-code to enable DCS onto the
0035  4153 ;           CPU control store bus.
0035  4154 ;        9. Initialize the RDM Control Register (RDCTRL) with zero.
0035  4155 ;       10. Set the bits TSTP (trap stop) and MSTP (master halt enable) in the
0035  4156 ;           RDM Control Register.
0035  4157 ;       11. Start the clock by clearing the bits CLKCN1 and CLKCN0 in the DCSCR
0035  4158 ;           which will execute the micro-code to:
0035  4159 ;                1. Load RTEMP1 with the data from the WD register.
0035  4160 ;                2. Load the VA with zero.
0035  4161 ;                3. Write the model instruction from RTEMP1 to cache.
0035  4162 ;                4. Increment the VA for the next address.
0035  4163 ;                5. Write zeros into this cache location to prevent cache
0035  4164 ;                   parity errors from trapping the IRD1 decode.
0035  4165 ;                6. Zero the PC which will initiate instruction prefetch.
0035  4166 ;                7. Execute a BUT/IRD1TST to load the IR and OSR.
0035  4167 ;                8. Execute a NOP.
```

```
0035  4168 ;                9. Execute a BUT/IRDX.
0035  4169 ;               10. Halt.
0035  4170 ;
0035  4171 ;           NOTE! - The micro-code above cannot be single stepped.
0035  4172 ;
0035  4173 ;       12. Execute the micro-code for the second IRDX without uADINH asserted
0035  4174 ;           in order to trap the generated address.
0035  4175 ;       13. Execute a masked comparison of the control store address trace
0035  4176 ;           register with the expected CS address.
0035  4177 ;       14. If the two are different signal an error.
0035  4178 ;       15. Otherwise continue looping from step 5 to step 14 till finished.
0035  4179 ;       16. Execute the micro-code to place the CPU back into native mode
0035  4180 ;           and enable the console CTRL-P interrupt.
0035  4181 ;       17. Exit.
0035  4182 ;
0035  4183 ; DATA PATTERNS
0035  4184 ;
0035  4185 ;       The input data patterns were derived from chapter 4.4 of the CPU
0035  4186 ;       micro-sequencer specification dated on 9/25/78. Because operand
0035  4187 ;       specifiers are embedded into compatibility mode instructions, certain
0035  4188 ;       instructions have more than one opcode decode. Model opcodes were
0035  4189 ;       generated by first using Chart 4.4.1B to obtain the base opcodes for
0035  4190 ;       each compatibility mode instruction. These opcodes were then enhanced
0035  4191 ;       to include all the possible decodes. The enhancements were obtained
0035  4192 ;       by changing the operands to specify both register and non-register
0035  4193 ;       modes and by using Chart 4.4.1A to modify the operands to get all
0035  4194 ;       possible instruction decodes.
0035  4195 ;
0035  4196 ;       The expected control store addresses where obtained from the
0035  4197 ;       Compatibility Mode Ird Rom Definition in the CPU micro-code.
0035  4198 ;
0035  4199 ;       The following is a table that shows the instruction being decoded for
0035  4200 ;       a range of loop counts:
0035  4201 ;
0035  4202 ;       NOTE! - This table is NOT the same as that for CM IRD1.
0035  4203 ;
0035  4204 ;       Loop            Instruction             Loop            Instruction
0035  4205 ;
0035  4206 ;       01 - 10         JSR                     96              FSUB

0035  4248 ;
0035  4249 ; LOGICAL DESCRIPTION
0035  4250 ;
0035  4251 ;       During an IRD1 in compatibility mode the CCS ROMs are fed addresses
0035  4252 ;       from the Compatibility Mode IRD1 and IRDX ROMs on the DPM. The DPM ROMs
0035  4253 ;       are addressed according to the following scheme:
0035  4254 ;
0035  4255 ;       Source          ROM Address Bits        Comment
0035  4256 ;
0035  4257 ;       CIR <7:0>       <10:3>                  Encoded opcode generated by the
0035  4258 ;                                               IRD gate array.
0035  4259 ;
0035  4260 ;       IRD1            <2>                     Distinguishes between the 1st
0035  4261 ;                                               operand and the 2nd operand or
0035  4262 ;                                               execution flows. 1 during IRD1
0035  4263 ;                                               0 otherwise.
0035  4264 ;
0035  4265 ;       IRD Counter <0> <1>                     Distinguishes between the 2nd
0035  4266 ;                                               operand and execution flows.
0035  4267 ;                                               0 when decoding OS2, 1 when
0035  4268 ;                                               transferring to execution flows
0035  4269 ;
0035  4270 ;       Register Mode   <0>                     1 if the operand being eval-
0035  4271 ;                                               uated specifies register mode.
0035  4272 ;                                               Generated by the IRD and PHB
0035  4273 ;                                               gate arrays.
0035  4274 ;
0035  4275 ;       In the case of a Compatibility Mode second IRDX, only execution flow
0035  4276 ;       addresses should be generated.
0035  4277 ;
0035  4278 ; ASSUMPTIONS
0035  4279 ;
0035  4280 ;       This test assumes the following logic has already been tested; the
0035  4281 ;       cache, XB's, the IR and the OSR.

0035        .SBTTL  "TEST   0DB     CM Second IRDX Instruction Address Decode Test 2
0035  4562 ;*******************************************************************************
0035  4563 ;++
0035  4564 ;
0035  4565 ; FUNCTIONAL DESCRIPTION
0035  4566 ;
0035  4567 ;       This test makes sure the proper control store addresses are generated
0035  4568 ;       for the second compatiblity mode IRDX. The test is implemented by using
0035  4569 ;       two data tables. The first table consists of assembled VAX compatibil-
0035  4570 ;       ity mode macro instructions. The second table consists of expected
0035  4571 ;       control store addresses for the second IRDX. This test decodes those
0035  4572 ;       instructions not done in test one due to insufficient RDM memory space.
0035  4573 ;
0035  4574 ; TEST ALGORITHM
0035  4575 ;
0035  4576 ;       The IRDX micro-order will assert micro-addresses onto the CS address
0035  4577 ;       bus which will cause the RDM to stop the processor clock. Thus if the
0035  4578 ;       first IRDX is executed using the FETCH and BRSTCLK pseudo-ops, the
0035  4579 ;       clock will stop before the IRDX is finished. This causes bad addresses
0035  4580 ;       to be generated for some of the macro instructions being decoded. To
0035  4581 ;       prevent this from happening, the LOADREG pseudo-op is used to execute
0035  4582 ;       the micro-code that fetches the macro instructions, loads the IR and
0035  4583 ;       OSR and does the first IRDX. The second IRDX can be executed using the
0035  4584 ;       FETCH and BRSTCLK pseudo-ops since the address that is generated will
0035  4585 ;       not depend on whether that micro-order finishes execution.
0035  4586 ;
0035  4587 ;       This test is executed in the following manner:
0035  4588 ;
0035  4589 ;        1. Initialize the CPU.
0035  4590 ;        2. Execute micro-code to place the CPU into compatibility mode,
0035  4591 ;           disable the console CTRL-P interrupt and zeroes the MDR in order
0035  4592 ;           to allow the IRDX to function.
0035  4593 ;        3. Initialize the WD register with zero.
0035  4594 ;        4. Prepare a loop for 49 instructions.
0035  4595 ;        5. Load the WD register with a model opcode from the opcode table
0035  4596 ;           indexed by the loop count.
0035  4597 ;        6. Take the CPU off the CS address bus and hold the CPU clock
0035  4598 ;           off by setting the bits uADINH, CLKCN1, CLKCN0, PARSTP, and PARCHK
0035  4599 ;           in the DCS Control Register (DCSCR).
0035  4600 ;        7. Load the DCS Address Counter (DCSAD) with the starting location of
0035  4601 ;           the test micro-code.
0035  4602 ;        8. Load the Control Store Address Match Register (CSAMR) with the
0035  4603 ;           starting address of the test micro-code to enable DCS onto the
0035  4604 ;           CPU control store bus.
0035  4605 ;        9. Initialize the RDM Control Register (RDCTRL) with zero.
0035  4606 ;       10. Set the bits TSTP (trap stop enable) and MSTP (master halt enable)
0035  4607 ;           in the RDM Control Register.
0035  4608 ;       11. Start the clock by clearing the bits CLKCN1 and CLKCN0 in the DCSCR
0035  4609 ;           which will execute the micro-code to:
0035  4610 ;                1. Load RTEMP1 with the data from the WD register.
0035  4611 ;                2. Load the VA with zero.
0035  4612 ;                3. Write the model instruction from RTEMP1 to cache.
0035  4613 ;                4. Increment the VA for the next address.
0035  4614 ;                5. Write zeros into this cache location to prevent cache
0035  4615 ;                   parity errors from trapping the IRD1 decode.
0035  4616 ;                6. Zero the PC which will initiate instruction prefetch.
0035  4617 ;                7. Execute a BUT/IRD1TST to load the IR and OSR.
```

```
0035  4618 ;                8. Execute a NOP.
0035  4619 ;                9. Execute a BUT/IRDX.
0035  4620 ;               10. Halt.
0035  4621 ;
0035  4622 ;           NOTE! - The micro-code above cannot be single stepped.
0035  4623 ;
0035  4624 ;       12. Execute the micro-code for the second IRDX without uADINH asserted
0035  4625 ;           in order to trap the generated address.
0035  4626 ;       13. Execute a masked comparison of the control store address trace
0035  4627 ;           register with the expected CS address.
0035  4628 ;       14. If the two are different signal an error.
0035  4629 ;       15. Otherwise continue looping from step 5 to step 14 till finished.
0035  4630 ;       16. Execute the micro-code to place the CPU back into native mode
0035  4631 ;           and enable the console CTRL-P interrupt.
0035  4632 ;       17. Exit.
0035  4633 ;
0035  4634 ; DATA PATTERNS
0035  4635 ;
0035  4636 ;       The input data patterns were derived from chapter 4.4 of the CPU
0035  4637 ;       micro-sequencer specification dated on 9/25/78. Because operand
0035  4638 ;       specifiers are embedded into compatibility mode instructions, certain
0035  4639 ;       instructions have more than one opcode decode. Model opcodes were
0035  4640 ;       generated by first using Chart 4.4.1B to obtain the base opcodes for
0035  4641 ;       each compatibility mode instruction. These opcodes were then enhanced
0035  4642 ;       to include all the possible decodes. The enhancements were obtained
0035  4643 ;       by changing the operands to specify both register and non-register
0035  4644 ;       modes and by using Chart 4.4.1A to modify the operands to get all
0035  4645 ;       possible instruction decodes.
0035  4646 ;
0035  4647 ;       The expected control store addresses where obtained from the
0035  4648 ;       Compatibility Mode Ird Rom Definition in the CPU micro-code.
0035  4649 ;
0035  4650 ;       The following is a table that shows the instruction being decoded for
0035  4651 ;       a range of loop counts:
0035  4652 ;
0035  4653 ;       NOTE! - This table is NOT the same as that for CM IRD1.
0035  4654 ;
0035  4655 ;       Loop            Instruction
0035  4656 ;
0035  4657 ;       01 - 04         MOVB
0035  4658 ;       05 - 08         CMPB
0035  4659 ;       09 - 0C         BITB
0035  4660 ;       0D - 10         BICB
0035  4661 ;       11              BISB
0035  4662 ;       12 - 15         SUB
0035  4663 ;       16 - 1D         JMP
0035  4664 ;       1E              RTS
0035  4665 ;       1F - 20         (unused)
0035  4666 ;       21              SPL
0035  4667 ;       22              NOP
0035  4668 ;       23 - 26         (reserved)
0035  4669 ;       27 - 31         SWAB
0035  4670 ;
0035  4671 ; LOGICAL DESCRIPTION
0035  4672 ;
0035  4673 ;       During an IRD1 in compatibility mode the CCS ROMs are fed addresses
0035  4674 ;       from the Compatibility Mode IRD1 and IRDX ROMs on the DPM. The DPM ROMs
```

```
0035  4675 ;       are addressed according to the following scheme:
0035  4676 ;
0035  4677 ;       Source          ROM Address Bits        Comment
0035  4678 ;
0035  4679 ;       CIR <7:0>       <10:3>                  Encoded opcode generated by the
0035  4680 ;                                               IRD gate array.
0035  4681 ;
0035  4682 ;       IRD1            <2>                     Distinguishes between the 1st
0035  4683 ;                                               operand and the 2nd operand or
0035  4684 ;                                               execution flows. 1 during IRD1
0035  4685 ;                                               0 otherwise.
0035  4686 ;
0035  4687 ;       IRD Counter <0> <1>                     Distinguishes between the 2nd
0035  4688 ;                                               operand and execution flows.
0035  4689 ;                                               0 when decoding OS2, 1 when
0035  4690 ;                                               transferring to execution flows
0035  4691 ;
0035  4692 ;       Register Mode   <0>                     1 if the operand being eval-
0035  4693 ;                                               uated specifies register mode.
0035  4694 ;                                               Generated by the IRD and PHB
0035  4695 ;                                               gate arrays.
0035  4696 ;
0035  4697 ;       In the case of a Compatibility Mode second IRDX, only execution flow
0035  4698 ;       addresses should be generated.
0035  4699 ;
0035  4700 ; ASSUMPTIONS
0035  4701 ;
0035  4702 ;       This test assumes the following logic has already been tested; the
0035  4703 ;       cache, XB's, the IR and the OSR.
0035  4704 ;
0035  4705 ; ERROR DESCRIPTION
0035  4706 ;
0035  4707 ;       Below is a table of possible error symptoms and their most likely
0035  4708 ;       causes:
0035  4709 ;
0035  4710 ;               Symptom                                 Probable Cause
0035  4711 ;       +-------------------------------+-------------------------------+
0035  4712 ;       | The received control store    |                               |
0035  4713 ;       | address is bad for one or sev-| One or several bad CM IRD1 and|
0035  4714 ;       | eral instructions, or shows   | IRDX ROMs.                    |
0035  4715 ;       | certain bits stuck at 1 or 0. |                               |
0035  4716 ;       +-------------------------------+-------------------------------+
0035  4717 ;       | The received control store    |                               |
0035  4718 ;       | address is bad for every      |                               |
0035  4719 ;       | instruction or branches to the| A bad IRD gate array.         |
0035  4720 ;       | CM.BAD.IRD address in the     |                               |
0035  4721 ;       | micro-code.                   |                               |
0035  4722 ;       +-------------------------------+-------------------------------+
0035  4723 ;       | Register mode fails to assert |                               |
0035  4724 ;       | causing the wrong address to  | A bad IRD or PHB gate array.  |
0035  4725 ;       | be generated.                 |                               |
0035  4726 ;       +-------------------------------+-------------------------------+
0035  4727 ;
0035  4728 ;       On error this test will call out the IRD and PHB gate arrays and will
0035  4729 ;       also type out the following data:
0035  4730 ;
0035  4731 ;       EXPECTED CONTROL STORE ADDRESS
```

```
                                0035  4732 ;       RECEIVED CONTROL STORE ADDRESS
                                0035  4733 ;       LOOP COUNT
                                0035  4734 ;       DATA RESERVED FOR INSTRUCTION
                                0035  4735 ;       OPCODE OF THE INSTRUCTION BEING DECODED
                                0035  4736 ;
                                0035  4737 ;--
                                0035  4738 ;*******************************************************************************************

Pass 2	3088	00:00:29.55	00:00:43.07
Symbol table output	32	00:00:00.22	00:00:00.22
Psect synopsis output	48	00:00:00.60	00:00:00.68
Cross-reference output	0	00:00:00.00	00:00:00.00
Assembler run totals	6987	00:02:04.79	00:02:38.11

The working set limit was 2048 pages.
1167893 bytes (2282 pages) of virtual memory were used to buffer the intermediate code.
There were 30 pages of symbol table space allocated to hold 357 non-local and 153 local symbols.
7801 source lines were read in Pass 1, producing 347 object records in Pass 2.
104 pages of virtual memory were used to define 49 macros.

Macro library statistics

Macro library name	Macros defined
DISK$UCODPACK00:[VAX750]COMETMAC.MLB;1	49
SYS$COMMON:[SYSLIB]STARLET.MLB;2	0
TOTALS (all libraries)	49

2057 GETS were required to define 49 macros.

There were 0 errors, 3 warnings and 0 information messages, on lines:
 3102 (1) 3795 (1) 4560 (1)
