CHIPS 82C574
MICROCHANNEL INTERFACE CHIP

- Compatible with IBM Microchannel specifications
- Provides highly integrated Microchannel interface solution
- Flexible Card ID assignment
- Supports POS registers
- Resource relocation capability to avoid address conflict
- Flexible Interrupt level selection

The 82C574 is a highly integrated Microchannel interface chip for IBM PS/2 personal computer application. It can be configured to operate in either of two modes; "mode 0" for 82C570 CHIPSLINK 3270 coaxial protocol controller or "mode 1" for the 8 bit general purpose I/O slave peripherals.

When mode 0 is selected, the chip decodes the I/O address of 02DXH and 022XH for IBM & IRMA registers and generates the IORD, IOWR signals for 82C570. It also decodes the memory space of 0CE000 to 0CFFFF for the display buffer and external micro code access by activating the MEMRD, MEMWR signals.

In mode 1 operation, the 82C574 supports the microchannel bus interface to most 8 bit I/O slave devices. The adapter I/O address can be programmable during the setup procedure. This resource relocation capability avoids conflicts with the adapter's address. The interrupt level can also be selected via software. The 82C574 greatly simplifies the circuitry to interface to the microchannel bus.

The 82C574 is fabricated using advanced CMOS technology and is packaged in a 68 pin PLCC.

82C574 Functional Description

The 82C574 block diagram is illustrated in Fig 1. The chip consists of the following functional blocks:

- POS Registers
- Peripheral Commands and Card Select Feedback Generator
- Resource Relocation Logic
- Card Channel Ready Signal Generator

POS REGISTERS

A total of 6 POS registers are supported by 82C574. These registers can be accessed only during configuration cycle by activating CDSETUP, M/IO to low. The description of each register are as follows:

1. 100H: Low Byte ID Register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID7</td>
<td>ID6</td>
<td>ID5</td>
<td>ID4</td>
<td>ID3</td>
<td>ID2</td>
<td>ID1</td>
<td>ID0</td>
<td></td>
</tr>
</tbody>
</table>

This register is read only. The reading of this register returns the content of pins ID7-ID0.

2. 101H: High Byte ID Register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID15</td>
<td>ID14</td>
<td>ID13</td>
<td>ID12</td>
<td>ID11</td>
<td>ID10</td>
<td>ID9</td>
<td>ID8</td>
<td></td>
</tr>
</tbody>
</table>

Read only register. The content of pins ID15-ID8 is returned when reading this register.

3. 102H: Miscellaneous Register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>X</td>
<td>X</td>
<td>X</td>
<td>RDYCTL</td>
<td>IRQSL1</td>
<td>IRQSL0</td>
<td>CDEN</td>
<td></td>
</tr>
</tbody>
</table>

Bits 7-4 are unused. The reading of these bits are “1”. Bit 3 RDYCTL is used in mode 1 to control the CDCHRDY signal generation. A “0” selects the synchronous extended channel cycle. A “1” selects the asynchronous extended cycle.

Bit 2-1 IRQSL1 and IRQSL0. They are used in mode 1 with the external 72LS156 demultiplexer to select the interrupt level.

Bit 0 Card Enable control bit. When this bit is “0”, the adapter is disabled. 82C574 responds only to setup IO read and write operations. It does not respond to the access of peripheral IO registers or memory.

Register 102H is readable and writable. All the bits are reset to “0” by RESET signal.

4. 103H: Low Byte Card Address Register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADR7</td>
<td>ADR6</td>
<td>ADR5</td>
<td>ADR4</td>
<td>ADR3</td>
<td>ADR2</td>
<td>ADR1</td>
<td>ADR0</td>
<td></td>
</tr>
</tbody>
</table>

The Card Address registers are read/write registers. They are used for resource relocation to avoid the adapter conflict. In case of the same adapter address, the host can reassign the board address. These two registers are used in mode 1 operation. To generate the IO read/write commands for the peripheral or to activate the CDSFBK or inactivate the CDCHRDY signals, the address from host A15 to A4 have to match ADR15 to ADR4, A3 to A0 may bypass the comparison with ADR3 to ADR0 if the individual mask bit is activated by forcing MASK3-0 pins to VSS. ADR15 is the most significant bit (MSB) and ADR0 is the least significant bit (LSB).

5. 104H: High Byte Card Address Register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADR15</td>
<td>ADR14</td>
<td>ADR13</td>
<td>ADR12</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADR11</td>
<td>ADR10</td>
<td>ADR9</td>
<td>ADR8</td>
<td></td>
</tr>
</tbody>
</table>

6. 105H: Mode Select Register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>X</td>
<td>X</td>
<td>X</td>
<td>MODSL3</td>
<td>MODSL2</td>
<td>MODSL1</td>
<td>MODSL0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 4-7 are unused. The reading of these bits are “1”. Bits 3-0 are used to select operation modes. Pattern 1010 is for mode 1: General Purpose 8 Bit I/O Slave Peripheral application. All other combinations of bit pattern are for mode 0 operation: 82C570 CHIPS LINK application. RESET signal resets all the bits to “0” which is mode 0 operation.

Register 105H is a read/write register.
PERIPHERAL COMMANDS AND CARD SELECT FEEDBACK GENERATOR

The peripheral read/write command is generated by decoding the IO or memory address, M/IO, S0, S1 status and gating with CMD signal.

Mode 0:

In this mode, both IO and memory operations are supported. For IO operation, the decoding of IO address 02DXH or 022XH will activate the IORD if S0 = 1 and S1 = 0 or IOWR if S0 = 0 and S1 = 1. For memory operation, the decoding of memory space of 0CE000 to 0CFFFF will generate MEMRD or MEMWR commands.

Mode 1:

The IO operation is supported in this mode. To generate the IO read/write commands, the address from host needs to match the relocation card address programmed in POS registers. (A0–A3 comparison can be bypassed by activating MASK3 to MASK0 individually.)

The Card Select Feedback (CDSFBK) is used to inform the host that the adapter is selected. It stays inactive during setup cycle. It is generated by decoding the IO address space and S0, S1 status. It should go active within 50 ns after Address, M/IO, MADE24 become valid and within 25 ns from the time status becomes active.

RESOURCE RELOCATION LOGIC

The resource relocation capability is supported in mode 1. The operation of this block was described in the POS REGISTERS section.

CARD CHANNEL READY GENERATOR

The basic channel cycle time in IBM PS/2 system is 200 ns. It can be extended by using CDCHRDY signal. There are two ways to extend the cycle: Synchronously or Asynchronously.

Mode 0:

When the host addresses the IO space of 02DXH or 022XH, the CDCHRDY will go low within 55 ns from the time M/IO, Address become valid (25 ns from the time status S0, S1 becomes valid) and then return to high within 25 ns after CMD becomes active. The bus cycle is extended from 200 ns to 300 ns, this is called synchronously extended.

If the host accesses the memory space of 0CE000 to 0CFFFF, CDCHRDY will go inactive just like IO access but it will stay low until a low to high transition on pin RDYIN is detected. This is called asynchronously extended bus cycle.

Mode 1:

The bus extention can be done in either way by programming the RDYCTL bit in POS register. If this bit is “0”, the bus cycle is extended synchronously to 300 ns. A “1” in this bit will extend the cycle asynchronously.
APPLICATION

Figure 2 shows the application diagram for 82C570 CHIPSLink 3270 protocol controller. The Card ID is selected by tying ID0 to ID15 pins to VCC or VSS. This provides a flexible choice. RDYIN from 82C570 is used to control the bus cycle for dual port RAM access. D0-7 are used during setup cycle. The 82C574 also provides the 74LS245 buffer chip select and direction control signals. Due to the high integration of both 82C574 and 82C570, only a few components are required to implement the solution for micro to mainframe communication in microchannel environment.

Figure 3 shows the application diagram for the 8 bit IO slave peripherals. In this mode, the resource relocation capability is provided. The interrupt level can be selected by software during setup cycle. The address 0 to 3 are also latched by the 82C574 for the peripherals.
